### EXPEDITION TO POINT BARROW, ALASKA.

### LETTER

FROM

# THE SECRETARY OF WAR,

TRANSMITTING,

In response to a resolution of the House, the report of the International Polar Expedition to Point Barrow, Alaska.

DECEMBER 16, 1884.—Referred to the Committee on Naval Affairs and ordered to be printed.

### LETTERS OF TRANSMITTAL.

WAR DEPARTMENT, Washington City, December 15, 1884.

The Secretary of War has the honor to transmit to the House of Representatives the report of the International Polar Expedition to Point Barrow, Alaska, together with the letter of the Chief Signal Officer of the Army, of this date, submitting the report to this Department, the same being furnished in response to the resolution of the House of Representatives of December 11, 1884, as follows:

"Resolved, That the Secretary of War be requested to transmit to the House of Representatives, if not inconsistent with the public service, the report of the International Polar Expedition to Point Barrow, Alaska, by Lieut. P. H. Ray, U. S. Army, for the years 1881, 1882, and 1883."

ROBERT T. LINCOLN,

Secretary of War,

The Speaker of the House of Representatives.

WAR DEPARTMENT,
OFFICE OF THE CHIEF SIGNAL OFFICER,
Washington City, December 15, 1884.

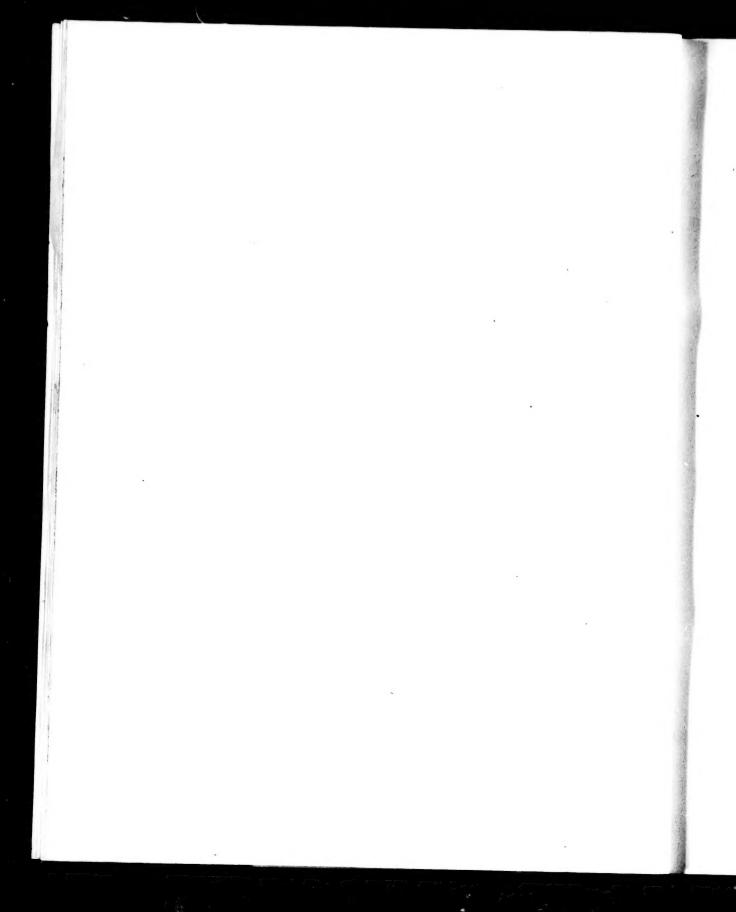

SIR: I have the honor to transmit herewith the report of the International Polar Expedition to Point Barrow, Alaska, called for by resolution of House et Representatives of December 12, 1884.

I am, very respectfully, your obedient servant,

W. B. HAZEN,

Brigadier and Brevet Major General, Chief Signal Officer, U. S. Army.

The Hon. Secretary of War, Washington, D. C.

### LETTER OF TRANSMITTAL.

WASHINGTON, D. C., November 1, 1884.

SIR: I have the honor to transmit herewith a full report of the operations of the International Polar Expedition to Point Barrow, Alaska, under my command, for the years 1881, 1882, and 1883.

The work in meteorology and magnetism is as complete as it was possible to make it with the means placed at my disposal.

The work of geographical exploration, having been made of secondary importance, was confined to such short expeditions as I was able to make from the home station, without suspending of interfering with the regular work; but enough was done to demonstrate that the work of exploration in the Arctic can be carried on, at any season of the year, with the assistance of the natives, with comparative safety and but very little suffering, and I trust that our experience will tend to remove some of the prejudices now existing in the public mind against Arctic exploration.

I regret exceedingly that I was not given more time to prepare myself for this undertaking, as my previous training had not been of such a character as to fit me for it, except in the matter of command and equipment.

I cannot speak too highly of the faithfulness and devotion of the members of the expedition to their duty. To their cheerful assistance and ready obedience is due all credit for the success attending the expedition.

In preparing this report I have been placed under many obligations to Prof. Spencer F. Baird, Director of the United States National Museum, and to Prof. J. E. Hilgard, Superintendent United States Coast and Geodetic Survey, for advice, as well as valuable assistance in their departments; also to Mr. Charles A. Schott, assistant. United States Coast and Geodetic Survey, for the reduction and discussion of the magnetic observations; to Mr. R. S. Avery, United States Coast and Geodetic Survey, for the reduction and discussions of tides; to Private A. L. McRae, Signal Corps, U. S. Army, for the reduction and discussion of the ground currents; and to Sergt. John Murdoch, Signal Corps, U. S. Army, naturalist of the expedition, for his able and valuable assistance throughout the whole expedition, and in preparing this report.

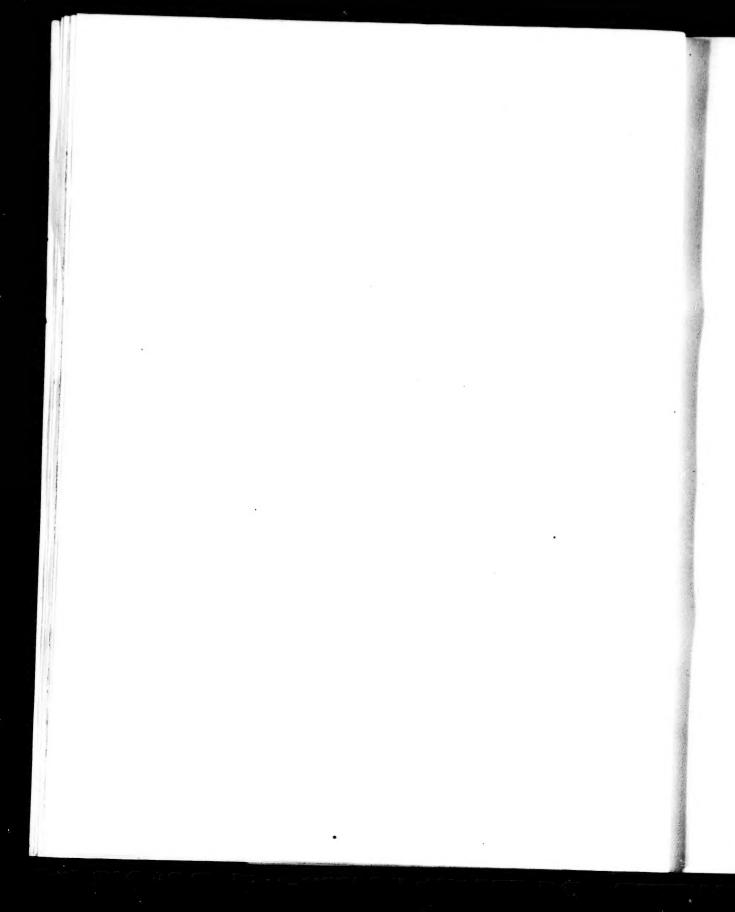

I am, very respectfully, your obedient servant,

P. H. RAY.

First Lieutenant Eighth U. S. Infantry, A. S. O., Commanding Expedition.

CHIEF SIGNAL OFFICER, UNITED STATES ARMY,

Washington, D. C.

## ORDERS AND INSTRUCTIONS.

[Special Orders No. 102.]

WAR DEPARTMENT, OFFICE OF THE CHIEF SIGNAL OFFICER, Washington, D. C., June 24, 1881.

[Extract.]

IV. By direction of the Secretary of War, the following-named officers, civilians, and enlisted men are assigned to duty as the expeditionary force to Point Barrow, Alaska Territory, viz: First Lieut. P. Henry Ray, Eighth Infantry, Acting Signal Officer; Acting Assistant Surgeon, George Scott Oldmixon, U. S. Army,; Sergt. James Cassidy, Signal Corps, U. S. Army, observer; Sergt. John Murdoch, Signal Corps, U. S. Army (A. M., Harvard), naturalist and observer; Sergt. Middleton Smith, Signal Corps, U. S. Army, naturalist and observer; Capt. E. P. Herendeen, interpreter, storekeeper, &c.; Mr. A. C. Dark, astronomer and magnetic observer (Coast Survey); one carpenter; one cook; one laborer.

V. First Lieut, P. H. Ray, Eighth Infantry, Acting Signal Officer, is hereby assigned to the command of the expedition, and is charged with the execution of the orders and instructions given below. He will forward all reports and observations to the Chief Signal Officer, who is charged

with the control and supervision of the expedition.

VI. As soon as practicable, Licutenant Ray will sail with his party from San Francisco for Point Barrow, latitude 71° 27′ north, longitude 156° 15′ West (Beechey), and establish there a permanent station of observation, to be occupied until the summer of 1884, when he will return here, unless other orders reach him. On the way out and back, a stoppage of a few days only will be made at Plover Bay (latitude 64° 22′ 0″ north, longitude 173° 21′ 32″ west), for the purpose of determining the error and sea rate of his chronometers. The vessel conveying him to his destination will not be detained at the permanent station longer than is necessary to unload the stores.

W. B. HAZEN,

Brigadics and Brevet Major-General, Chief Signal Officer, U. S. Army.

Official:

LOUIS V. CAZIARC.

First Lieutenant, Second Artillery, Acting Signal Officer.

[Instructions No. 76.]

WAR DEPARTMENT, OFFICE OF THE CHIEF SIGNAL OFFICER, Washington, D. C., June 24, 1881.

The following general and detailed instructions will govern in the establishment and management of the expedition organized under Special Orders No. 102, War Department, Office of the Chief Signal Officer, Washington, D. C., dated June 24, 1881.

The permanent station will be established at the most suitable point in the vicinity, and, if practicable, at or in the immediate neighborhood of Point Barrow, Alaska Territory, (latitude 71° 27' north; longitude 156° 15' west, as determined by Beechey).

The chronometers will be rated at San Francisco, and will have their sea rates determined by an observation of time at the United States Coast and Geodetic Survey station at Plover Bay (latitude 64° 22′ 6″ north; longitude 173° 21′ 32″ west).

The vessel should, on arrival at the permanent station, discharge her eargo with the utmost dispatch, and at once be ordered to return to San Francisco, Cal. Before permitting the vessel to leave, a careful examination of the vicinity will be made and the exact site chosen for the permanent station will be located in latitude and longitude, chronometrically, both by Lieutenant Ray and by the navigator of the vessel independently, and a report in writing will be sent by the returning vessel. By the same means will be sent a transcript of all meteorological and other observations made during the voyage, and also a list of apparatus and stores known to be broken, missing and needed, to be supplied next year.

After the departure of the vessel, the energies of the party should first be devoted to the erection of the houses required for dwellings, stores, and observatories.

Special instructions regarding the meteorological, magnetic, tidal, pendulum, and such other observations as were recommended by the Hamburg International Polar Conference, are transmitted herewith.

Careful attention will be given to the collection of specimens of the animal, mineral, and vegetable kingdoms. These collections are to be made as complete as possible, and are to be considered the property of the Government of the United States, and are to be at its disposal. The collections in natural history and ethnology are made for, and will be transferred to, the National Museum.

It is contemplated that the *permanent* station will be visited in 1882, 1883, and 1884 by a steam or sailing vessel, by which supplies for, and such additions to, the present party as are deemed needful will be sent. Lists of stores required to be sent by the next season's vessel will be forwarded by each returning boat.

The subject of fuel and native food supply, its procurement and preservation, will receive full and careful attention, as soon after the establishment of the post as practicable. Full reports upon this subject will be expected.

A special copy of all reports will be made each day, which will be sent home each year by the returning vessel.

The full narrative of the several branches will be prepared with accuracy, leaving the least possible amount of work afterwards to prepare them for publication.

In case of any fatal accident or permanent disability happening to Lie tenant Ray, the command will devolve on the officer next in seniority, who will be governed by these instructions.

W. B. HAZEN,

Brigadier and Brevet Major-General, Chief Signal Officer, U. S. Army.

Official:

LOUIS V. CAZIARC,

First Lieutenant, Second Artillery, Acting Signal Officer.

INSTRUCTIONS FOR THE COMMANDING OFFICERS OF THE INTERNATIONAL POLAR STATIONS OCCUPIED BY THE SIGNAL SERVICE.

#### I. General.

 Regular meteorological and other observations will be maintained uninterruptedly, both at sea and at the permanent station, in accordance with instructions issued to Signal Service observers and those contained in the accompanying extract from the proceedings of the Hamburg conference, to which special notes are appended where needed.

2. The original record of these observations will be kept in the blank books supplied for this purpose, and a fair copy of the corrected and reduced results will be made upon Signal Service and special forms, as supplied in bound volumes.

ed by 3. At sea a daily record will be kept, by dead reckoning and astronomical observations, of r Bay the latitude and longitude of the vessel, by which the positions at the times of meteorological observations will be deduced, and on arriving at the permanent station the local time and longitude itmost will be immediately determined, whence the Washington and Göttingen times will be found by vessel applying the correction for longitude.

4. All meteorological and tidal observations will be made at exact hours of Washington civil time. (The longitude of Washington Observatory is 5<sup>h</sup> 8<sup>m</sup> 12<sup>k</sup>,09 west of Greenwich.) The regular magnetic observations will be made at even hours and minutes of Göttingen mean time. (Göttingen is 0h 39m 46°, 24 east of Greenwich, or 5h 47m 58°, 33 east of Washington; whence 12 noon Washington time is simultaneous with 5h 47m 58s.33 p. m. Göttingen time, or 6h 12m 1s.67 a. m. Washington time is simultaneous with 12 noon at Göttingen.)

If hourly meteorological observations of all these phenomena cannot be taken, then, if possible, take bi-hourly observations at the hours 1, 3, 5, 7, 9, 11 a, m. and p. m., or at least six observations at 3, 7, and 11 a. m. and p. m. On no account will the meteorological observation at 7 a. m., Washington time, be omitted.

5. Upon arrival at the permanent station the local time and longitude will be determined at once, without waiting for the erection of permanent shelters which will be built for the meteorological, magnetic, and astronomical instruments, according to the plans and material as specified.

The meteorological and astronomical observatories will be located conveniently near to the dwelling of the observers, but that of the magnetic observatory will be determined by the consideration that these instruments must be removed from all danger of being affected by the presence of steel or iron, including galvanized and tinned iron. If needed to keep off intruders, a guard or fence should surround the magnetic observatory.

6. The observation of tides will be made as complete as possible in summer by a gauge on the shore, and in winter through an opening in the ice, according to the instructions furnished by the Superintendent of the United States Coast and Geodetic Survey. The necessity for observing the tides will suggest that the dwelling-house should be located as near the sea as is safe and convenient.

7. In addition to the ship's log and the official journal of the party, to be kept by the commanding officer, and the official record of observations, to be kept by the meteorological, magnetic, tidal, and astronomical observers, each member of the party will be furnished with a diary, in which he will record all such incidents as specially interest him. This diary will not be open to inspection until delivered to the Chief Signal Officer for his sole use in compiling the full record of the expedition.

8. Accurate representations, either by the photographic process or sketching, will be made of all phenomena of an unusual character, or of whatever is characteristic of the country.

9. Carefully prepared topographical maps will be made of as much of the surrounding country as is practicable.

11. Detailed instructions concerning observations, instruments, and time, by the INTERNATIONAL POLAR CONFERENCE, HAMBURG, 1879, OCTOBER 1 TO 5.

[Translated at the office of the Chief Signal Officer, with added notes in brackets.]

1. OBLIGATORY OBSERVATIONS IN THE DOMAIN OF METEOROLOGY

No. 17. Temperature of the air.—The mercurial thermometers should be graduated to twotenths degrees Centigrade, and the alcohol thermometers to whole degrees, and both verified at a central meteorological station to within one-tenth degree Centigrade.

The thermometers furnished are graduated to Fahrenheit; they have been compared with the Signal Service standard, and are provided with correction cards.

No. 18. The instruments should be placed at an altitude of between 1.5 and 2.0 meters (5 to 6 feet), and it is recommended that they be exposed in a double shelter of lattice work, according to

H. Ex. 44--2

e perenant by the other roken,

erecother

fransvegeonsid-

be forve full eports

ar by least

com-

TIONS

th at rvers ence,

this and Wild's method. The outer shelter to be of wood, the inner of metal. The observations of minimum thermometers can be made under various conditions.

|The shelters furnished consist of an outer wooden lonvre work and an inner galvanized iron shelter, both framed so as to be easily set up. The minimum temperatures at various altitudes above ground will be observed, and under such various conditions as circumstances suggest.

No. 19. The alcohol thermometers ought to be compared at the station of observation with the standard mercurial thermometer at the lowest possible temperatures.\*

No. 20. Sea temperatures should be observed, whenever possible, at the surface and at each 10 meters (about 33 feet) of depth; as instruments, proper for this observation, the following may be specified: deep-sea thermometers, as manufactured or invented by Ekmann; Negretti & Zambra; Miller-Casella; Jamsen.

|While at sea the temperature of the surface water will be observed hourly, with the Signal Service water thermometer, by the ordinary methods, and the temperature at each 33 feet of depth, whenever practicable; for greater depths, one of the above deep-sea instruments will be used.

No. 21. The point 0° Centigrade (32° Fahrenheit), for all the thermometers should be determined from time to time.

[The testing of thermometers will be made quarterly, according to the usual Signal Service rules.]

No. 22. Pressure of the air.—At each station there must be at least two well-compared mercurial barometers, a reserve barometer, and an aneroid.

No. 23. The standard barometer ought to be compared or read once each day.

[Several mercurial and ancroid barometers are furnished, and all regular observations will be made from a mercurial barometer, selected from among them, which will be compared, once each day, with the standard barometer. All barometers will be fully compared with the standard once each month; such comparative readings will be entered on the regular Signal Service forms for this purpose.]

No. 24. Humidity.—The psychrometers (i. c., dry and wet bulb) and hair hygrometer will be used with Regnault's dew-point apparatus as a check, according to Wild's instructions.

[Comparative readings, with these instruments, will be frequently made and carefully preserved for future study.]

No. 25. The wind.—The wind-vane and Robinson's anemometer are to be read from within the house (see the method of construction of the apparatus of the Swedish station at Spitzbergen), at the same time; the force of the wind will be estimated according to the Beaufort scale and the wind-direction to sixteen compass points, referred to the true meridian.

[The points of the compass on the wind-dial will be adjusted to the true meridian as is ordered for all Signal Service stations; self-registering instruments of the Signal Service pattern for the velocity and direction of the wind to eight points will be used. A record of wind-force on the Beaufort scale (0 to 12), and wind-direction to sixteen points will also be kept and will be entered in the special column.]

No. 26. To aid in deciding the question whether the Robinson's anemometer, with large or with small cups, should be used for determining the force of storms in the Polar zone, it is recommended that both such be subjected to preliminary experiments.

[Anemometers of the Signal Service pattern, having small cups and short arms, are the only ones that it is convenient to furnish. For comparative purposes keep two of these in permanent daily use, exposing them in different but good localities. The extra anemometers should be compared with these during twenty-four hours on the first Monday of each month, and a full record be kept of such comparisons.]

No. 27. The clouds.—The amount of cloudiness and the direction of the movement of all clouds should be observed to sixteen compass points.

[In addition, the kinds of clouds will be noted, and the record kept in the usual Signal Service form.]

<sup>\*</sup>For notes on special thermometers, prepared for the Signal Service stations, see Section III of these instructions

ions of No. 28. Precipitation.—The commencement and duration of rain, snow, hail, &c., and, when possible, the amount of precipitation, is to be observed. As to the amount, however, this is not obligatory in winter.

[There will be recorded regularly, and, if practicable, hourly, the amount of precipitation.]

measured if possible, otherwise estimated.

No. 29. The weather.—Storms, thunder-storms, hail, fog, frost, dew, &c., and the optical phenomena of the atmosphere ought to be recorded.

2. obligatory observations in the domain of terrestrial magnetism.

No. 30. Absolute determinations.—For declination and inclination it is necessary to attain an accuracy of 1.0 minute, for horizontal intensity of 0.001. The proper instruments are, for example, the portable theodolite of Lamont and the ordinary dip-needles.

No. 31. The absolute observations must be executed in close connection and synchronous with the readings of the variations instruments, in order to be able to reduce the data given by the latter to an absolute normal value, and to determine the zero point of the scales. The determinations must be made so frequently that the changes in the absolute value of the zero point of the scales of the variations apparatus can be accurately checked thereby.

No. 32. Observations of variations.—These ought to include the three elements and be made by means of instruments, with small needles, in contrast to the apparatus of Gauss. In order to obtain an uninterrupted reciprocal control, two complete sets of variations instruments are desirable, and recommended, in order to avoid any interruption of the observations, by reason of breakage, derangement, &c.

[One set of these instruments is now provided, but a second set may be sent in 1882.]

No. 33. The horizontal intensity in one, at least, of these systems should be observed with the unifilar apparatus. Because of the magnitude of the perturbations to be observed, the scales of the variations instruments must have at least a range of ten degrees, and the arrangements are to be so made that the greatest possible simultaneity of the readings may be achieved.

No. 34. During the entire period of occupancy of the station the variations instruments will be read hourly. It is desirable that two readings be made; for instance, just before and after the full hour, with an interval of a few minutes between.

No. 35. Weyprecht presented the following separate note on this point:

"Since it appears to me that in these regions of almost perpetual disturbances, hourly readings, made at moments not well defined, are insufficient to establish mean values accurately expressing the local perturbations for a given epoch (which data ought to serve as a means of comparison with other localities), and in consideration of the slight increase of labor which will be caused by taking readings at precise moments, I cannot agree with the views of the majority of the Conference."

"I state that at least the expedition conducted by myself will take readings hourly of all three variations instruments at 58<sup>m</sup> 0\*, 59<sup>m</sup> 0\*; 60<sup>m</sup> 0\*; 61<sup>m</sup> 0\*; 62<sup>m</sup> 0\*; Göttingen mean time."

"WEYPRECHT."

[Observations will be taken as specified by Weyprecht.]

No. 36. As term days, the first and fifteenth day of each month will be observed from midnight to midnight, Göttingen time. The readings will be taken at intervals of five minutes, always on the full minutes, and the three elements are to be read with all possible rapidity, one after the other, in the following order: 1. Horizontal intensity; 2. Declination; 3. Vertical intensity.

No. 37. For these term days, the plan of magnetic work should comprehend continuous readings, for instance, readings every twenty seconds—throughout one whole hour—even though only one magnetic element be observed. It is the opinion of the Conference that the observations should begin so that one of the hours of observation shall agree with the first hour of the 1st of January, and that during the entire period of magnetic work the hours devoted to this continuous observation should be changed on each successive semi-monthly term day.

Signal

<sup>\*</sup>For special instructions in magnetic work, furnished by the Superintendent of the United States Coast and Geodetic Survey, see Section IV of these instructions.

No. 38. The accuracy of the magnetic observations should be such as to give the declination to the nearest minute and the horizontal and vertical intensity in units of the fourth decimal place.

No. 39. On the term days, observations of auroras are also to be made continuously. Moreover, auroras are also to be observed from hour to hour throughout the period of magnetic observations, and especially in reference to their form and momentary position in altitude and true azimuth. The intensity of the light is to be estimated on a scale of 1, 2, 3, 4.

No. 40, Isolated auroral phenomena must be made the subject of thorough observations in connection with which the various phases are to be noted simultaneously with readings of the magnetic variations instruments.

[Those of the party not engaged at the magnetic instruments will observe and record auroral phenomena.]

No. 41. Since the greatest possible simultaneity in the readings is a point of the highest importance, the determinations of the location and of the time are to be made with instruments having firm foundations (such as the universal instrument or astronomical theodolite, the vertical circle, zenith telescope, astronomical transit, &c.); this, however, does not exclude the use of reflecting instruments of a superior class. By all means, therefore, must efforts be made to determine the geographical position, and especially the longitude of the station, as soon as possible after it has been occupied.

[The first approximate longitude of the station, as determined by chronometers, will be checked as frequently as possible by lunar distances, occultations, &c., and the value adopted in the daily work of the station will be revised as often as necessary, preferably at the end of each quarter. The details of the magnetic observations will be regulated according to the instructions published by the Superintendent of the United States Coast and Geodetic Survey.]

#### 3. ELECTIVE OBSERVATIONS.

No. 42. The Conference recommends the following observations and investigations most earnestly to the consideration of all those to whom is intrusted the preparation of instructions for an expedition or who themselves are assigned to such work.

No. 43. Meteorological.—The diminution of temperature with altitude, the temperature of the earth, of the snow, and of the ice at the different depths should be determined.

[The forms of the snow-crystals should be recorded by careful drawings; the amount of hoar-frost accumulated on some well-exposed object should be measured by the use of the scales furnished by the medical department. Apparatus is ordered to be provided for the preservation of air and of air-dust for future analysis.]

No. 44. Observations of insolation (or solar radiation) are to be made, as well as observations on spontaneous evaporation, which latter can be made during the winter by weighing cubes of ice, and during the summer by the evaporimeters.

[A shallow circular vessel of water, whether fluid or frozen, exposed to the open air and sunshine, should have its loss of weight determined, daily or oftener, by delicate scales.]

No. 45, Magnetical.—From time to time absolute simultaneous readings of all three elements of terrestrial magnetism must be made in order to accurately determine the ratio between the simultaneous changes of the horizontal and those of vertical intensity.

No. 46. Galvanic carth currents.—Observations are desired of earth currents in intimate connection with magnetic observations and the auroral phenomena.

[Telegraph lines of well-insulated wire, extending a short distance north and south and also east and west, and furnished with resistance coils and deflection needles, are supplied, and every effort should be made to carry out these observations.]

No. 47. Hydrographic incretigations.—Observations of the direction and strength of the ocean currents and the movements of the ice.

No. 48. Deep sea soundings and observations upon the physical properties of the sea water, for instance, determination of the temperature, specific density, gaseous contents, &c., and these objects should be especially kept in view in the selection of a vessel for the expedition. Observations on tides, when possible, should be made with the self-registering apparatus.

[With regard to tidal observations, the instructions published by the United States Coast and Geodetic Survey are to be followed. Glass-stoppered bottles are provided for preserving specimens of sea water to be brought back for examination.]

No. 49. Parallax of the aurora.—Determination should be made of the altitude of the aurora by means of measurements made for example with the meteorograph, which must be made by small detached parties of observation, having also, if possible, one party observing simultaneously the variations of magnetic declination.

[Particular attention will be paid to determining the apparent position in altitude and azimuth of bright meteors and shooting stars and of definite portions of the aurora borealis, and to drawings of the appearances presented by the phenomena, as seen by observers situated as far apart (say one-half to five miles) as possible; in these drawings the auroral phenomena should appear in their proper positions relatively to the horizon, meridian, fixed stars, &c., and to that end each member of the party, without exception, will learn the names and configurations of the stars shown upon the map of stars furnished you. A supply of these maps is furnished, sufficient to allow of using them as base charts upon which to enter the observed phenomena in special cases. Attention is called to the points of inquiry suggested in the Annual Report of the Chief Signal Officer, 1876, pp. 301–335.]

No. 50. Observations of, 1, atmospheric electricity; 2, astronomical and terrestrial refractions; 3, length of the simple second's pendulum; 4, observations on the formation and growth of floating ice and glaciers.

[Attention is called to the observations on the formation of ice made by Nares and other explorers. The pendulum observations will be made in accordance with special Coast Survey instructions.]

No. 51. Observations and collections in the realms of zoology, botany, geology, &c.

[The instructions given by Prof. Spencer F. Baird to the naturalist will be followed by him.] No. 52. There will also be made special observations relating to the whole polar problem, such as the flight of birds, presence of drift-wood, and from what direction it came, and other matters as may suggest themselves from time to time and be found practicable.

#### III. SPECIAL INSTRUCTIONS RELATIVE TO CARE AND USE OF SPECIAL THERMOMETERS.

[See paragraph 19, page 10.]

The construction of the minimum standard thermometers designed for the Arctic stations having been intrusted to the Thermometric Bureau of the Winchester Observatory of Yale College, the astronomer in charge of that institution furnishes the following special instructions, which will be earefully followed:

"NEW HAVEN, May 30, 1881.

"GENERAL REMARKS AND DIRECTIONS CONCERNING THE SIGNAL SERVICE MINIMUM STAND-ARDS, NOS. 1 TO 12 INCLUSIVE, CONSTRUCTED BY THE WINCHESTER OBSERVATORY OF YALE COLLEGE.—J. AND H. J. GREEN, MECHANICIANS.

"Materials.—The alcohol, carbon di-sulphide, and ethyl oxide used are as pure as the chemical processes will admit. For thermometric purposes they may be assumed chemically pure. There is no more air above the liquid columns than is accidentally admitted in the process of scaling the tubes. In this respect these standards are different from the ordinary spirit thermometers. It is probable that the great parity of the alcohol will render it nearly as valuable for temperatures below—80° Fahrenheit—as the carbon and ether thermometers.

"Directions for carriage.—It is highly desirable that these thermometers should be kept, as nearly as possible, in the same condition as on leaving the observatory. For this purpose they have been carefully packed in a vertical position, and care must be taken to see that they are so repacked, with the bulb down. Owing to the low boiling points of the other and carbon disulphide they are not (probably) accurate at temperatures above + 60° Fahrenheit, but they will remain clear and limpid at temperatures below zero, at which the alcohol thermometers may (but

iter, for d-these bservahardly probably) show viscidity. It is desirable, therefore, that preference be given to these standards over any other standards for extremely low temperatures, and in establishing the meteorological observatory at which the greatest cold is expected, special attention should be given to the other and carbon disalphide thermometers.

"Suggestions in their use.—Before mounting these thermometers in their stations, they should be carefully swung or jarred so that no spirit can be detected (with a magnifying glass) adhering to their upper ends. They should be inclined (with the bulb end nearest the ground) as far as it is safe, and have the index stand in its place, by its own friction against the side of the tube, so

that the draininge may be as perfect as possible.\*

"All readings should be recorded in millimeters, and it should be remembered that the accompanying tabular corrections (see the correction cards) are meant to give only approximate temperatures. A careful comparison of all the thermometers from 1 to 12 has been made between 0 and 90° and Nos. 1, 5, and 9 have been kept by the observatory for experiments at temperatures below 0° F.

"These are probably the best thermometers ever sent into the Arctic regions, and special care should be taken to insure the safe return of the records, and, though less important, the instruments."

IV. SPECIAL INSTRUCTIONS PREPARED BY THE UNITED STATES COAST AND GEODETIC SURVEY FOR OBSERVATIONS IN TERRESTRIAL MAGNETISM AT POINT BARROW AND LADY FRANKLIN BAY.

[These instructions will be applied, when suitable, to the observations ordered in preceding pages, but they will also furnish a guide to the minimum number of observations to be taken in case of accidents occurring to prevent full compliance with the plan proposed by the International Polar Commission.]

As soon as the quarters of the expedition have been fixed upon, a magnetic house will be erected, in which the regular magnetic observations, as described below, will be made; other observations will be made when on boat or sledge trips.

Instruments.—For use at the magnetic observatory, there will be provided a magnetometer, for absolute and differential declination and for horizontal magnetic intensity, to be permanently mounted on a stone pier. In connection with this instrument a meridian or azimuth mark will be established a short distance off the observatory, and visible from it through an opening in the wall. The astronomical bearing of this mark will be carefully determined by means of an altazimuth instrument and solar or stellar observations.

In the same house, but on a separate pier, will be mounted a Kew dip circle, and in the case of Point Barrow, a third instrument, a bifilar magnetometer, will also be permanently mounted on its pier. At Point Barrow the magnetometer (or uniflar) and the bifilar instruments will be mounted in the magnetic meridian and at a distance of not less than twelve feet, and the dip circle will be mounted equidistant from these instruments, forming an equilateral triangle. At Lady Franklin Bay the two instruments will be mounted in the plane of the magnetic prime vertical, and not less than twelve feet apart. No iron is to be used in the construction of these buildings, and they should be not nearer than fifty yards to any other building, or double that distance to any large mass of iron. Special reading-lamps (of copper) must be provided for use with the instruments, and they must be tested to make sure that they do not affect the position of the magnets. The use of candles stuck into wooden blocks is preferable to using lamps.

When on boat or sledge journeys the party will carry a chronometer, a small alt-azimuth instrument with circles of about three inches diameter (as constructed by Fauth & Co., of Washington, or by Casella, of London), provided with a magnetic needle or compass mounted over its vertical axis, and a dip circle.

Observations at the permanent station.—Hourly observations will be made, for declination and diurnal variation, with the magnetometer on three consecutive days about the middle of each

<sup>\*</sup> This method conforms to that followed at all signal stations with minimum thermometers, except as to degree of inclination, wherein these suggestions should be most carefully followed.

azimuth Co., of nounted

ion and of each to degree month; besides these observations, extending over seventy-two hours, there will be made at any convenient intermediate time each day (of the three) one set of deflections, followed immediately by a set of oscillations for the determination of the horizontal intensity. At Point Barrow the bifilar will be read immediately after the unifilar. There will also be made at any intermediate time each day (of the three) a set of dip observations. In connection with the declination, the mark will be read once each day (unless the instrument should accidently be disturbed), but it suffices to determine the magnetic axis of the declination magnet on one of the three days. The instrumental constants of the magnetometer will be determined before leaving Washington, and the observers will use the Coast and Geodetic Survey magnetic blank forms for their records, or, in case no special forms are provided, they will use small (octavo) note books; they will also compute, as soon as the observations are completed, each month, the magnetic mean declination, diurnal range, and turning hours, also the horizontal force in absolute measure (English units) and the ip, tabulating the results for each day.

Extra observations on other than the three days about the middle of each month will be made during all occurrences of auroral displays, but as they are likely to be very numerous at Point Barrow, observers there may confine their extra observations to the more conspicuous displays only. On these occasions the declinometer (and the bifilar at Point Barrow) will be read, say, every ten minutes, or at shorter or longer intervals, as the state of the needle may appear to demand, the object being to establish a connection between the appearances of the aurora and the motion of the magnetic needle.

When landing on a boat journey, or during a sledge journey at suitable stations (not less than ten or fifteen miles apart), the time, latitude, and azimuth will be determined by the alt-azimuth instrument, and the declination by the same instrument (the hour and minute of the observation is to be noted, in order that the diurnal variation may be allowed for); the dip will also be observed, and in case time is pressing, reversal of circle, reversal of face of needle, and reversal of polarity may be dispensed with, but the needed correction to the result, from the single position of the instrument, must be ascertained at the permanent station. Observations of deflections (with magnetic needle and with weights) will be made with the dip circle, as arranged for relative and absolute total force, the data for the latter to be supplied at the permanent station.

It is highly desirable, especially in the case of the Lady Franklin Bay party, that all stations within reach and formally occupied by other parties for magnetic purposes be revisited, in order to furnish material from which to deduce the secular change during the interval; besides, all opportunities should be taken when landing on the way up to secure observations for declination, dip, and intensity—the latter best poscillations of the intensity magnet. The winter quarters of the late English expedition show the connected magnetically with the present quarters.

[All magnetic observations will be made on Göttingen time, as provided for by the Hamburg Conference.]

All magnetic records will be kept strictly in conformity with "Notes on Measurements of Terrestrial Magnetism," United States Coast Survey, Washington, 1877, and other records in connection therewith should be equally clear and complete, and all computations should be made by the observer in separate books. Duplicates of all records will be made, compared with the original, and the latter returned, annually, if practicable, to the Chief Signal Officer for the Superintendent of the Coast and Geodetic Survey, Washington, D. C. The observers should also provide themselves with copies of the "Admiralty Manual of Scientific Enquiry," the "Arctic Manual and Instructions," 1875, and "Aurore, their characters and spectra," by J. R. Capron, 1880, also with "Terrestrial and Cosmical Magnetism," by E. Walker, 1866, and any other work they may require for their information.

#### V. ADDITIONAL SPECIAL INSTRUCTIONS.

The rules prescribed in "Instructions for the Expedition toward the North Pole," as published (in pamphlet) by authority of the Hon. George M. Robeson, Secretary of the Navy, and those contained in "Suggestions Relative to Objects of Scientifle Investigation in Russian America," both of which are furnished, will be followed as closely as circumstances permit.

#### VI. MEMORANDUM OF OUTFIT.

LIST OF APPARATUS TO BE FURNISHED TO POINT BARROW, AND WITH SOME EXCEPTIONS
AND ADDITIONS TO LADY FRANKLIN BAY.

#### GEOGRAPHICAL AND ASTRONOMICAL APPARATUS.

One surveyor's compass and tripod; one 100-feet chain or steel tape; one prismatic compass; one set of pins; one altitude and azimuth, 6-inch circles; one meridian transit, about 2 or 3 inches aperture; two extra level tubes for low temperatures for meridian transit; three sextants; three artificial horizons; eight marine chronometers (mean time); one marine chronometer (sidereal); two pocket chronometers (mean time); one house (astronomical observatory), plan to be supplied; charts of the Alaska coast from the United States Coast and Geodetic Survey.

Magnetic apparatus.—One complete magnetometer—Fauth & Co.—unifilar declinometer—eatalogue No. 70, price \$400, extra light needles and mirror for auroral disturbances; one Kew dip circle, large size; one bifilar magnetometer; one magnetic observatory building. (See plan.)

Tidal apparatus.—One level and staff; two pulleys and weight and float; fifty glass-stoppered bottles for specimens of sea-water.

Pendulum apparatus.—Pendulum apparatus will be carried and used by a special temporary party from the United States Coast and Geodetic Survey.

[Deep sea sounding .- Will be left to the United States Coast Survey.]

Meteorological apparatus.—One instrument shelter of open wooden louvre work, made in sections (see plan); one inner thermometer shelter of open galvanized iron louvre work, made in sections (see plan); twelve mercurial thermometers, ordinary stem divided; two metallic thermometers: twelve spirit thermometers, ordinary stem divided; six mercurial thermometers, maximum stem divided; six spirit thermometers, minimum stem divided; six special minimum thermometers, from Yale College; four psychrometers, mercurial, wet-bulb; one dew point apparatus; Regnault's as modified by Alluard, with extra thermometers for low and high temperature; six water thermometers and three cases, Signal Service pattern, for surface temperatures; two pairs Marie-Davy's conjugate thermometers for solar radiation; two pairs Violle's conjugate bulbs for solar radiation (will be sent next year); two Hicks's thermometers for terrestrial radiation (will be sent next year); two mercurial marine barometers; four mercurial cistern barometers (Green, Signal Service pattern), large bore, reading to thousandths; three aneroid barometers (Casella's make); two hair hygrometers; two self-registers, one double and one single, for an emometers and an emoscopes (Signal Service pattern-Gibbon or Eccard); six extra attached thermometers for barometers; six extra barometer tubes for barometers; four rain-gauges, two copper and two galvanized iron; six divided sticks for measuring rain and snow; ten pounds pure mercury; four anemometers (Robinson's); four arms and cups and four spindles, for Robinson's anemometer, for repairs; two vanes, small; one large vane, complete; one Eccard contact (interior); ten battery cells (Eagle) and supplies for same for three years; two thousand yards insulated wire; four telephones and two call bells; one galvanometer for obstruction of ground carrents; one hundred feet cable for the double self-register; four box sounders; one delicate scale and one medicine chest (from medical department); apparatus for collecting air and atmospheric dust; six dark lanterns for observers' use (brass or copper).

Signal apparatus.—Two Grugan's heliographs; four sets signal kits complete; six signal code cards.

Blank books and forms.—Twelve diaries for 1881, 1882, and 1883, respectively, one to be kept by each man; two hundred and fifty books for original record of meteorological observations; fifty blank books for magnetic observations, allowing two pages daily and extra pages on special days; fifty blank books for daily journal, for miscellaneous observations; twenty-five blank books for tidal observations, allowing one page daily; twenty-five blank books for astronomical observations.

<sup>&#</sup>x27;If practicable these will be rated at various temperatures at the Horological Bureau of the Observatory of Yale College,

vations; fifty volumes, Form 4, for copy of original record; three hundred star charts, for auroras, &c.; one hundred forms for comparison of barometers; eight hundred forms for anemometer register.

Books.-Instructions to Observers, Signal Service, U. S. Army; Annual Reports of the Chief Signal Officer, from 1873 to 1880, inclusive; Loomis's Treatise on Meteorology; Buchau's Handy Book of Meteorology; Kämtz's Meteorology (Walker's translation); Mohn's Meteorology (original German): Schmid's Meteorology (original German); Smithsonian Instructions for register of periodical phenomena; Smithsonian Miscellaneous Collections, Vol. I; Guyot's Meteorological and Physical Tables; Crelle's Multiplication Tables; Blanford's Indian Meteorologist's Vade Mecam, Parts I, II, III; Loomis's Practical Astronomy; Church's Trigonometry; Chanvenet's Practical Astronomy; Bowditch's Navigator; Bowditch's Useful Tables; Lee's Collection of Tables and Formula: American Nautical Almanac for 1881, 1882, and 1883; Admiralty Manual of Scientific Inquiry, 4th ed.; Admiralty Manual and Instructions for Arctic Expedition, 1875; Nares's, &c., Reports of English Arctic Expedition; Nares's Narrative of Voyage to Polar Sea, London, 1878; Dall's Meteorology of Alaska from Pacific Coast Pilot, United States Coast Survey; Dall's Resources of Alaska; Harkness on Sextants, United States Naval Observatory, observations for 1869, Appendix 1, pages 51 to 57; Charts, United States Hydrographic Office, No. 68, and British Admiralty, Nos. 593, 2164, 2435; Chambers's Descriptive Astronomy; Bremiker's edition of Vega's Logarithmic Tables: Barlow's Tables; W. S. Harris's Rudimentary Magnetism; Coast Survey Papers on Time, Latitude, Longitude, Magnetics, and Tidal Observations; Everett's Translation of Deschanel; Jenkin-Electricity and Magnetism, 4th ed., New York, 1879; Reports of the United States Fish Commission on Dredging; Sigsbee on Deep-Sea Sounding, &c. (United States Coast Survey Report): Markham's Collection of Papers Relating to Arctic Geography, London, 1877; Schott's Reduction of Observations of Hayes and Sountag; Schott's Reduction of Observations of Dr. Kane; Schott's Reduction of Observations of McClintock; Manual of Military Telegraphy; Myer's Manual of Signals; J. R. Capron, Aurora: their characters and spectra; E. Walker, Terrestrial and Cosmical Magnetism; Pope's Modern Practice of the Electric Telegraph; Instructions for the Expedition toward the North Pole, from Hon. George M. Robeson, Secretary of the Navy; Suggestions Relative to Objects of Scientific Investigation in Russian America; stationery as ordinarily supplied; drawing paper and instruments.

All officers and observers of the expedition are charged to at once familiarize themselves in detail with these instructions, and in the practice of the duties they prescribe, together with a thorough knowledge of the instruments and their use; and commanding officers are specially charged to see that these requirements are observed.

Official memorandum to accompany instructions No. 76.

## NARRATIVE.

On the 18th day of July, 1881, at ten o'clock in the forenoon, we sailed from San Francisco, Cal., on board the schooner Golden Fleece, a staunch little schooner of one hundred and fifty tons burden, and, being towed outside the heads, we began our voyage in the teeth of a strong northwest gale; and it was three days before the reefs were shaken out of our sails.

The expedition, on the day of sailing, was organized as follows: First Lieut. P. H. Ray, Eighth Infantry, commanding; Act. Asst. Surg. George S. Oldmixon, U. S. Army, surgeon; E. P. Herendeen, interpreter; Sergt. James Cassidy, Signal Corps, U. S. Army, observer: Sergt. John Murdoch, Signal Corps, U. S. Army, observer; Sergt. Middleton Smith, U. S. Army, observer: Mr. A. C. Dark, astronomer; Vincent Randit, carpenter; Albert Wright, cook; Frank Peterson, laborer, With one exception, all were strangers to me, and I subsequently had occasion to regret that more time was not given and care exercised in selecting the personnel, especially those intended for the scientific work. For even with experienced observers it is very difficult to do accurate work in this high latitude.

The voyage was uneventful. Owing to adverse winds and calms, it was not until August 9 that we raised the high lands of the Aleutian peninsula to the eastward of Ounimak Pass. A succession of calm days left us at the mercy of the currents, which here are strong to the eastward, and carried us in sight of Kadiak, before a breeze sprung up that would enable us to bear up for the pass. We entered it on the afternoon of the 15th, when the wind fell, but the tide serving, we drifted through during the night. After entering Behring Sea we had stronger winds, and after clearing the pass we were enabled to stand on our course, which carried us about sixty miles to the eastward of the Pribyloff Islands.

On the morning of the 19th we sighted the island of Saint Mathews, passing three miles to the eastward of it, its highest peaks only showing above the fog. We were favored with fair, strong winds from this time on until we arrived at Plover Bay, Siberia, where we anchored at 6 p. m. August 21. The weather being stormy, we were unable to get a sight of the sun until the 24th, when a series of excellent observations were obtained. This delay proved fortunate for us, for on the 22d the U. S. revenue steamer Corwin came into the harbor for coal. Her master, Captain Hooper, reported the ice very light in the lower latitudes of the Arctic Ocean: o much so that he had been enabled to reach Wrangel Land, a point never heretofore attained. To him we became indebted for a fine supply of reindeer clothing and tents, which he had collected in view of a possibility of his wintering in the Arctic. The supply came very opportunely, as we had been mable to obtain any deer-skins at San Francisco and were depending upon sheep-skins for our winter clothing.

We found that our chronometers were running steadily and well, and, after laying in a supply of fresh water, were towed outside the harbor by the Corwin on the morning of the 25th. The wind dying away suddenly, left us at the mercy of the current, which was setting strong to the northward, and during the night we drifted through the straits, getting only a glimpse of the Diomede Islands and East Cape as we passed, as we were enveloped in a dense fog the most of the time. While at Plover Bay we obtained from the natives a quantity of most excellent trout, which proved an agreeable addition to our sea fare.

After passing the straits we encountered strong northeasterly winds, which retarded our progress very much. We sighted Cape Lisburne on the afternoon of August 31, and soon after it came on to blow so heavily that the vessel was hove to, and in that position rode out the gale. For over forty-eight hours we were unable to have fires on board for any purpose whatever. The force of the gale having abated on the 3d of September, we stood to the southeast, the weather remaining so thick that we were unable to obtain a sight of the sun to determine our position. On the 7th we sighted key Cape, and then stood along shore to the northeast, keeping the land aboard until we sighted the point on the afternoon of September 8, and came to anchor about one mile to the northeast of Cape Smythe, thus successfully accomplishing the first and most important stage of our week.

The voyage, though long and tedious, had been remarkably free from any accidents, and the meager comforts of our little schooner grew wonderfully luxurious when compared with the low desolate shore, which we could occasionally eatch a glimpse of through the drifting snow.

Point Barrow, situated in latitude 71° 23′ north, longitude 156° 40′ west, the destination of the expedition, was first discovered by Mr. Elson, master in H. M. S. Blossom, commanded by Captain Beechey, in Angust, 1826; and is graphically described by him in his report of his memorable voyage, made to the Pacific and Arctic Sea, during the years 1825, 1826, 1827, and 1828.

In the lapse of sixty years but few changes have taken place on this coast. The people of the generation that Captain Beechey met have all passed away, and the story of the coming of the first white man is one of the legends of the band of Nuwükmeun. The next visit made by white men was that of Captains Dease and Simpson, of the Hudson's Bay service, who, in July, 1837, started from Fort Good Hope, and by boat passed down the Mackenzie to the sea, and along the northern shore as far as Return Reef, the point where Franklin was turned back by meeting with impassable ice, in 1826. They here found the ice fast on the land, and further progress by boats being impossible, Captain Simpson accomplished the remaining distance on foot, and thus succeeded in determining the coast line of the northern shore from Behring Straits to the mouth of the Mackenzie. H. M. S. Plover, Captain Magnire, wintered at Point Barrow the winters of 1852, 1853, and 1854, since which time the coast has been frequently visited by vessels of the American whaling fleet.

Upon arriving at the point we at once set about finding a suitable location for the observatory. At the extremity of the point is the village of Nuwuk, which occupies all the land that is free from inundation by the sea. To locate the observatory among their buts would entail endless trouble and annoyance. Between the village and the mainland, three miles away, is a low, barren sandbank, from forty to one hundred yards wide, across which, during a westerly gale, the sea breaks when open. To the south and west of this the land gradually rises, until at Cape Smythe it is fully thirty feet above the sea; but here again we found the most suitable ground occupied by the village of Uglaamie, a cluster of about twenty-three winter huts. We were unable to go any distance back from the beach, as we had no means of transporting our stores by land, and the marshy condition of the country would have prevented us from going any distance back from the beach even if we had the facilities. A point about twelve feet above the sea level, lying between the sea and a small lagoon three-fourths of a mile northeast from Uglaamie, was finally selected. The soil was firm and as dry as any unoccupied place in that vicinity, and, as it was marked by mounds of an ancient village, would be free from inundation. The lateness of the season gave us but little time for deliberation. The young ice was already forming, and the migration of the birds about over. It was on the morning of the 9th of September that the work of debarkation was commenced in a driving storm of snow and a northeast gale.

The lumber for the house and observatories was rafted alongside the vessel and warped ashore. This work was difficult and arduous, owing to the heavy surf on the beach, and the ice being some distance off shore, the strong northeast wind blowing at the time got up considerable sea, the spray froze wherever it struck, so the lumber was coated with ice as soon as it was taken out of the water. There was too much surf to use our boats, and it was not until the 13th, whea the wind fell, that we were able to commence putting the stores ashore. A temporary wharf was constructed, so the boats could be discharged without putting them on the beach. The natives, who at first appeared bewildered at the idea of our coming to stay, showed every disposition to be friendly now, and rendered us valuable assistance with their large skin boats (umiaks), and also

in carrying stores up from the beach. After one or two attempts at petty thieving had been firmly and quietly checked, they showed no disposition to commit any depredations upon our property. Though it was snowing heavily, the work of landing stores was pushed with the utmost vigor, as the wind was very light from the southwest and the sea was quiet, and we could land the umiaks on the beach without the fear of staving them, so that on the morning of the 15th the party was moved on shore into tents. We landed the last of the cargo during that afternoon, and the Golden Fleece was cleared the following morning, and sailed at 12 o'clock. She was the last link that bound us to civilization, and we knew that nearly a year must roll around before we could hope to hear from the civilized world again; but I did not see a single despondent face among the little party as they turned from watching the gallant little vessel out of sight to their work.

At the same time the stores were being landed the foundation of the house was laid. This was made safe and solid by excavating down to the frost, a distance of a little over one foot, and the sills and floor timbers firmly shored with blocks cut from pieces of drift-wood. Plates 1 and 2 give a ground plan and elevation of house. The bastion on the northwest corner was constructed from pieces of wreckage and drift-wood, and was pierced for musketry below and for the Gatling gun above. As soon as the house was inclosed and roofed the stores were all moved in, except a supply for about siz months, which was placed in a tent as a reserve in event of the loss of the main building by fire. The party moved in on the 22d, to put up the ceiling and partitions. We were obliged to bring the lumber in and pile it around the stove, so as to melt off the ice before, we could work it.

Winter came on rapidly; the lagoon, near the station, was closed entirely on the 26th; the weather continued stormy and thick until the sea closed toward the last of November. The work of carrying the stores and coal from the beach up to the site of the station (a distance of about one hundred yards) was very laborious, there being over one hundred tons of it besides the lumber, and we never for one moment caught sight of the sun from the time we landed until the 28th of September, and then only for a few moments. As soon as the house was made inhabitable we turned our attention to getting the instruments into position. We commenced taking hourly observations in meteorology on October 15, and in magnetism on December 1.

The transit and magnetic instruments were temporarily mounted on wooden piers, which were constructed in the following manner: Timbers sixteen inches square were cut to the proper length and placed on end in position in the observatories, the earth being removed so that the lower end rested on the perpetually frozen earth; they were cemented in their place by pouring water around them and allowing it to freeze. They remained firm and never altered their position in the slightest degree. The ice was found to be intact when the piers were taken down the following July, to be replaced by brick.

Every clear night the sky was illuminated by the most beautiful displays of aurora it has ever been my fortune to witness; they always commenced in the northeast and northwest, and seemed to spring from a dark low bank of clouds. The lights were never stationary for a single second, neither did they ever take the form of bows or arches so often seen in other latitudes, but great curtains of light flashing with all the prismatic colors seemed to be drawn across the heavens, ever rising and-changing and often culminating in a corona at the zenith, falling like a shower of meteoric fire. As the winter advanced these displays were more brilliant, and were always of a character that defies description, either by pen or pencil, as they were never for two seconds alike. They were anaccompanied by any sound so far as we were able to observe, and the deadly stillness that always prevails in this region when the sea was closed gave us an excellent opportunity to detect any sound had there been any.

During the last days of September, when the ice on the fresh-water ponds and lakes was from ten inches to one foot thick a sufficient quantity was cut, hauled to the house and conveniently piled, for winter use.

In December, as soon as the drifted snow was sufficiently hard to cut into cakes, covered ways were constructed leading to the observatories, and the ice piled so that during severe weather no person was obliged to go into the open air to carry on the regular work of the station.

Life at the station now settled down into the dull monotony of the routine work; hourly

observations in meteorology and the three elements of magnetism were carried on without interruption. To insure the health of the party each member was required to take exercise daily in the open air.

In January, 1882, work was commenced on a shaft for the purpose of getting the temperature of the earth, the results of which are given in Part V. The formation for the whole distance was sand and gravel, mingled with a deposit of drift-wood and marine shells, showing that each stratum represented the successive lines of ancient sea-shores. The earth was saturated with water. At a depth of thirty-five feet a deposit was found of clear water, unmixed with earth, too salt to be congealed at a temperature of + 12, which was the unvarying temperature of the earth at this depth. At a depth of twenty feet a tunnel was run to the east a distance of ten feet, and at the end of it a room ten by twelve was excavated out of the hard frozen ground. In this the temperature never rose above 22°. The walls were always dry and free from moisture, and the accumulation of hoar frost was very light. Here we stored whatever fresh meat, in the way of ducks, reindeer, wairus, or seal, that we were able to accumulate beyond our daily consumption. Our main supply was c.der-ducks, which, during the spring flight in May, were easily killed. We took four hundred in 1882, and five hundred in 1883; we found them excellent food, and when stored in the subterranean store-house they were at once frozen solid, and would keep for any length of time.

Fresh meat is the great safeguard against scurvy in this region; I never saw a trace of it among the natives, and meat is their only food. The immunity of my party from all disease or sickness of any kind I deemed was owing to the fact that through our own exertions, and with some assistance from the natives, we were seldom without it.

In March, 1882, I made a trip into the interior, an account of which I submitted in my report of last year. Some narrow leads opened in the ice to the north and west of the point on the 20th of April, and the natives reported seeing whales passing to the northeast on the 23d of the same month, and they were seen passing in the same direction every day from that time until June 15: that seemed to terminate their northern migration, as we saw no more of them until August 15, when they were seen going to the southwest along the edge of the pack. It is at this season that most of the whales are taken, as it is impossible for the vessels to follow them into the ice during their northern migration.

In the spring of 1882 eider-ducks were first seen on the 27th of April flying to the northeast, tar out over the ice, and a few straggling flocks were seen from time to time until May 12, when they appeared in immense numbers flying low along the shore ice to the northeast. This migra-

tion continued until about June 1, and then almost entirely ceased.

About the time the first flights along shore were seen a number of male king eider were found on the land, apparently exhausted from long flight and want of food. Some were caught and brought in alive, but they were generally dead when found, and always in an extremely emanciated condition. All species were represented in this flight, the king, Pacific, spectacled, and stellers. The Canada goose was never seen; but a few brent, white-fronted, and snow or arctic geese came at this season and stopped with us through the hatching season, bringing forth their young on the mainland. The eider duck, with but few exceptions, continued their flight to the north and east. During July and August large numbers of the males were constantly flying to the westward over Perigniak, a point about four miles to the southwest of Point Barrow. The fact that they came from the breeding-grounds was shown in the naked condition of the breast of some of those taken, the down having been plucked away to construct their nests. Those killed at this season were poor and unpalatable compared to those killed in the spring. But the natives take great numbers of them at this point at this season of the year; one often sees half a dozen families here in camp for that express purpose. Their methods of taking them will be found fully described in the chapter devoted to ethnology.

By the last of June the tundra was nearly free from snow, and narrow leads of water were open along shore. The few hardy flowers indigenous to this high latitude were in bloom, and conspicuous among them were the buttercup and dandelion. There was also a small yellow poppy, named by the natives "tūkāitūkāid jaksūn," which is also the name given by them to a small

VIEW OF THE STATION FROM THE WEST, WITH THE CREW OF THE "NORTH STAR" IN CAMP.

batterily that appears at this season. The butterily appears as the poppy fades, and they believe that the poppy is transformed, takes wings, and flies away.

On the afternoon of the 25th of June a vessel hove in sight to the southwest. She appeared to be in the solid pack, as there was no water in sight, but we soon discovered she was working her way along a narrow lead, about six miles from shore, which was not visible to us. At about 8 o'clock that night she was bearing about west true from the station, when she came to a halt; I at once dispatched interpreter Herendeen off to her. He returned the next day at 11 a. m., and reported that it was the steam-whaler North Star, (Captain Owen), on her first voyage from New Bedford. He brought a few letters and a file of New York papers, giving us news from the outer world. It was the first information we had of the death of President Garfield and loss of the Rogers. On the 27th I went out to her; found her fast in the ice, with no sign of open water in sight from her mast-head. Captain Owen reported she had suffered a severe nip the night before, and she was raised up bodily about four feet while I was on board of her. I visited her again on the 4th of July and she was still uninjured. During the night of the 6th the wind hauled around to the eastward, causing the pressure to slacken up, and several large cracks opened in the ice, one of them in close proximity to the ice-bound ship. Early on the morning of the 7th we saw she was afloat and working through the broken ice toward shore; when about two and a half miles from the station she again became fast, and lay there all night. The following day (July 8) the pressure again slacked and a lead opened along shore past where she was laying; she got under way and steamed slowly along the lead to the southwest. After proceeding a couple of miles she again became fast; the ice closing in from the west, she was now caught between the ground-ice and the great pack which was setting bodily to the northeast. She remained immovable from about noon until 4 p. m., when our attention was suddenly attracted to her by a great outcry raised by her crew, and we could distinctly hear the cracking of her timbers as her sides were crushed in by the ice; her masts fell a few moments after, and her crew escaped to the ground-ice. I at once set off to their assistance with what men could be spared from the station; we found they had saved nothing but their clothing, a cask of bread, and three boats; the few remaining fragments of the wreck were fast disappearing in the distance, being carried away by the moving pack. The crew all safely reached the land that night, being ferried across the open leads by the boats from the station; tents were pitched to shelter them, and every care given to their comfort. Captain Owen subsequently went out with his crew and brought in the bread, and boats to be used in moving to the southward along the shore-lead, in the event that no other vessel should be able to reach the station. On July 14 other ships fortunately hove in sight, and the wrecked people were distributed through the fleet, between that time and August 2, the last going on board the bark Thomas Pope, bound for San Francisco. Different vessels of the fleet remained in sight of the station off and on until September 23, the steamer Bowhead being the last to visit the station. We sent by her our last mail to the United States.

On August 2 a small schooner was seen coming around the point to the north and east, which proved to be the relief vessel Leo, Lieutenant Powell in charge.—She had been carried out of her course to the northeast by the current, in a thick fog; her master, being ignorant of the dangers attending navigation along this shore, having allowed her to drift into a position where, but for the providential springing up of a light breeze, she would certainly have been lost.—By her we received three additional observers, Sergt, J. E. Maxileld and Privates Charles Ancor, and John Guzman, of the Signal Corps, U. S. Army; a year's additional supply of provisions and coal; also the new magnetic instruments. With the help of the natives, she was discharged on the 26th, and sailed the following day.—I relieved and sent back by her Sergt, James Cassidy, Signal Corps, U. S. Army.

The new magnetic observatory was at once put up and the instruments mounted upon permanent brick piers, and observations with them commenced September 12.

Now that the ships were gone and all connection severed with the outside world, we had nothing to break the old routine of our duty at the station but the occasional visit of a native from some distant village. The faces of those living at Nuwūk and Üglaamie had become as familiar to us as those of our own people; they had ceased to be intrusive, but visited us almost daily with some curio or game for barter; and as the season advanced rud water became scarce we were daily besieged by the seal-hunters coming in from the sea and begging for a drink of water, of which

H. Ex. 44----4

there is a great scarcity after the frost has sealed up all sources of supply. The scarcity of fuel, together with their inadequate means for melting ice and snow, causes them to suffer under a constant water famine from October to July, and they seemed to think that our supply was never failing.

During the fall of 1882 we experienced none of the heavy westerly gales so common in 1881, and the main pack, though always in sight, did not come close in, and the sea along shore froze over comparatively smooth save for the small floes that were always drifting to and fro with the current. This remained unbroken until January, when a heavy westerly gale drove in the old ice to the three-fathom bar, which here lies parallel with the coast and about one and one-half miles from it. Inside this bar the ice formed to a thickness of five and one twenty-fourth feet, and a vessel might have wintered with perfect safety at the anchorage off the station in four fathoms of water. Both the winters we were there, about two and one-half miles to the sonthwest and three miles to the northeast, the old ice came in on the land with great force. In November and December the snow galleries were again constructed to the observatories, and the winter's work went on uninterruptedly. Observations of temperature in sea-water ice were carried on, and a series of tidal observations were made extending through a period of one hundred and twelve days. These observations were taken on the open coast, and go to show that the open Arctic Sea is practically tideless, the mean rise and fall being only about two-tenths of a foot. (Report on tides.)

A peculiar disturbance was observed frequently during these observations. There would be a sudden rise and fall of from three to five hundredths of a foot, like a sudden wave. These occurred when the sea was entirely closed, with not a trace of open water in sight, and apparently in no way connected with the regular action of the tide. There would also be a variation in the height of the water of from four to five fect, often extending through a period of from seven to ten days, but in no manner affecting the normal rise and fall.

During the winter of 1882-'83 temperature of the sea-ice was taken in the following manner: The thermometer was secured in a wooden box 6 by 6 by 15 inches, with a sliding door; this was placed in the ice one hundred yards from the beach, where the sea was smoothly frozen over, one foot below the surface, and frozen in so that the bulb was frozen solid in the ice.

The temperature of the sea-water was taken top and bottom through the hole at the tide-gauge in three fathoms of water. The results are given in the meteorological tables submitted with this report. I found that the second winter with its long night was much more trying upon the spirits and strength of the party than the first; the novelty had now worn off; there was no longer anything new or strange to interest them and there was no relief from the monotony of the routine of the regular work, and there is none so wearisome and wearing as this, without any change and without hope, for we had positive knowledge that there could be no change for us until our work was finished; so the slow time dragged on; days into weeks, months into years; so that exploration, or any work that required action, would have been hailed with joy. After the return of the sun I made parations for a trip into the interior, to locate geographically some of the discoveries made last year. I had by this time secured one excellent team of eight native dogs, and the sied made at Saint Michael's, given me by Sergeant Nelson in 1881, still being strong and serv reable, I was well equipped for inland work.

Everything being ready, I left the station at 5.30 a.m., March 28, with Mr. A. C. Dark, assistant, a native guide Apaidyao, and his wife. A team of eight dogs and one sled was our only means of transportation: and on it we carried our instruments, arms and ammunition, camp equipage, twenty days' supply of coffee, sugar, hard bread, and pennnican, a small kerosene stove, and one gallon of oil. The sled was rigged with a small lug sail, which was a great help with a fair wind. We traveled along the smooth shore ice to the southwest about eight miles after leaving the station, when we came to where the pack had come in onto the land, and the ice on the sea was too rough and broken for our sled. We here took to the tundra and traveled parallel to the shore until we reached the mouth of a small stream about ten yards wide, coming in from the southeast, called Siñaru, which has its source in a lake seven miles inland. We here left the coast, our general course being—suth, crossing the lake at the head of Siñaru, which I found to be seven miles across, and camped at 6 p. m. on a small stream flowing to the northeast; marched thirty-seven miles. Dark, ass our only mp equipstove, and vith a fair aving the a was too hore until ist, called r general es across, les. The country after leaving the coast was flat, and in the summer must be almost entirely covered with water, as we traveled the whole afternoon over a series of small lakes without seeing a single elevation of land that was over five feet above the surrounding country. Saw but few signs of reindeer and no natives, but saw where a hunting party had been in camp a few days before. Our dogs hauled their load with ease, though there was over seven hundred pounds weight on the sled. Weather clear, with light northeast wind.

March 29 .- Snowing heavily this morning when we broke camp at 6 a.m. After traveling four miles we struck a stream about thirty yards wide, within a narrow valley, flowing to northeast. Natives gave it the name of Iuaru. The storm broke at ten o'clock and the sun came out by eleven. The country grew more rolling and broken, and at 12 m. we came in sight of Meade River, which here flows through a valley about one and one-half miles wide, with bold bluffs on either bank from forty to sixty feet high; obtained a meridian sight of the sun at noon for latitude and a fair sight for time during p. m. Traveled up the river on the ice six miles and then left it on our right; crossed a neck of land eight miles wide and struck it again at a point where a large stream called Usûuktu comes in from the eastward, with a channel about forty yards wide and high, bold banks. Here we again traveled on the ice to a point four miles above the mouth of Usûktu, and camped at 4.30 p. m. on the left bank of the river; marched fifty-three miles. I found an Uglaamie native here in camp; he was engaged in fishing, and told us his nets were set just opposite to the camp. We obtained from him some fine whitefish; having no rifle he had been unable to take any deer. I ascended the bluffs on the right bank, which were here fifty feet high. On them found the ruins of several winter huts, built entirely of turf; the natives say that three generations ago all this region was inhabited by a people that lived by fishing and hunting reindeer, and cid not come to the coast, but that the deer and fish grew scarce and there came a very cold season and the people nearly all died from cold and starvation; the few that survived went away to the Colville or joined the little bands on the coast, so that now this whole region is not inhabited and is never visited except by the hunters from Nuwük and Uglaamie, who come here for deer during the menths of February and March; each year a few fish are also taken with gill-nets in the deep holes along Meade River, the fish being here confined by the river freezing solid on the bars; all movement of water on this water-shed is suspended during the winter, there being no rainfall or melting of snow from October to May, and springs are unknown.

March 29.—Broke camp at 6 a. m.; weather clear and moderate. Continued the march in a southerly direction along the river-bed four miles, when we left it, climbing some high bluffs on the lert bank to get on the level plain above and avoid the windings of the river; traveled parallel with its general course all day, crossing it twice, and camped at 5 p. m. on a small tributary of Meade River, and about six miles from the main stream. Marched twenty-five miles: during the afternoon passed a high bluff which is a noted landmark among the natives and known as Nūa-suk-nan; it is in latitude 70° 37′ N., longitude 157° 11′ W., and rises from fifty to seventy-five feet bove the surrounding country and is visible for many miles around. Camped to-night with Mù'ñialu, a native whom I had furnished with a rifle and ammunition to kill deer for the station. Found he had a fine supply on hand, and he very proudly showed us ten as our share. Got excellent sights of the sun during the day for latitude and longitude. Saw several large bands of reindeer and our guide succeeded in killing two. Temperature last night + 16°; during day rose to 29°.2.

March 31.—Weather cold and stormy, and as we are in a very comfortable snow-house we conclude to lie over for the day. My guide has never been beyond this camp, and I can see he has no desire to add to his knowledge of the geography of this region, so I have made arrangements with Michialu to go on with me. They were busy at work to-day preparing their sleds to haul in their venison to the settlement on the coast; their manner of doing it I have never before seen noted. The sleds which they use for this purpose are made from drift-wood fastened with whale-bone and raw-hide lashing; they are about ten feet long, two feet wide, and the runners eight inches wide and one and one-half inches thick, straight on top and no rail; they are shod for ordinary use with strips of bone cut from the whale's jaw-bone, and sometimes with walrus ivery; but this would not do in hauling a heavy load over the snow where there is no beaten trail, so they are shod with ice in the following manner: From the ice on a pond that is free from fracture they cut the pieces the length of a sled runner, eight inches thick and ten inches wide; into these

they cut a groove deep enough to receive the sled-runner up to the beam; the sled is carefully fitted into the groove, and secured by pouring in water, a little at a time, and allowing it to freeze. Great care is taken in this part of the operation, for should the workmen apply more than a few drops at a time, the slab of ice would be split and the work all to do over again; after the ice is firmly secured the sled is turned bottom up and the ice-shoe is carefully rounded with a knife, and then smoothed by wetting the naked hand and passing it over the surface until it becomes perfectly glazed; the sled when ready for use will weigh over three hundred pounds, and they load them with the carcasses of from seven to nine deer, weighing over one hundred pounds each. Men, women, and children harness themselves in with the dogs to haul these loads to the coast, often the distance of one hundred miles and over, seldom making more than eight or ten miles each day.

April 1.—The weather being clear, we improved the opportunity to determine accurately our

position. Observations were made for time, latitude, and declination.

April 2.—Broke camp at 8 a. m. with Mû/ñĭalu for guide; traveled south thirteen miles parallel with Meade River, which we struck at the confluence of a small stream coming in from the westward. For the last six miles the country had become much more rolling and broken, and at the point where we struck the river to-day the bluffs were over one hundred feet high and showed successive layers of turf and sand, where the action of the river had cut them away during the freshets in the summer. I noticed one stratum of turf five feet thick fifty feet below the surface. There was not sufficient moisture in the sand between the strata of turf to cause it to solidify under the action of the frost. On the bars in the river we found a few fragments of fossil ivory; a fringe of scrub arctic willow skirted the bank of the stream, but no drift-wood of any size was seen. Traveling now became quite difficult, as the river was too winding for us to follow its course by traveling on the ice, so we kept a southerly course, climbing the bluffs, where practicable, to cut off the bends. The dogs became tired out early in the afternoon, and we were finally obliged to go into camp on the ice under the lee of a high bluff on the right bank of the river. Marched twentythree miles. Before dark I climbed to the summit of the bluff, which was one hundred and seventy-five feet above the river, and could see a low range of mountains, running nearly east and west, about fifty miles away. From the break of the country, I have no doubt Meade River has its source in that range, so I named them Meade River Mountains. The native guide notified me upon my return to camp that he did not wish to go further south; that he was unacquainted with the country, never having been so far in the interior before. Beyond this he peopled the country with imaginary enemies. Nothing I could offer would induce him to go further. As I could not well get along without their help in dragging the sled up the hills, I was obliged to make this my turning point, much against my will. We saw no signs of deer, wolves, or any game after we struck the foot-hills; the range of the reindeer seems to be the flat country we had crossed to the north.

April 3.—Broke camp at 8 a. m. and returned to Mû'ñialu's camp, reaching there at 4 p. m. Weather clear. The san on the snow fields affected our eyes very seriously in spite of the shaded glasses we wore, and the natives were affected equally as bad as ourselves.

April 4.—Lay over in camp, having our boots dried and repaired and getting ready for the return journey. Weather clear and cold.

April 5.—Broke camp at 5,30 a. m. Traveled on our outward trail to camp No. 2 and slept in the lut we used on our way out. Weather clear and cold, with very little wind.

April 6.—Broke camp at 6 a.m. Followed old trail back to camp No. 1. Weather bright and clear; suffered intensely all day from my eyes, becoming so inflamed I could scarcely see. Mr. Dark does not seem to be so seriously affected. Temperature fell last night to  $-13^{\circ}.4$ ; during the day,  $-24^{\circ}.$ 

April 7.—Broke camp at 5.30 a. m., and reached the station at 5 p. m. Was obliged to travel with my eyes bandaged; Apaidy ao was also nearly blind. No person can be exempt from this terrible suffering who travels in this region at this season of the year; the blinding glare of the sun upon the snow affects the strongest eyes, and we found no preventive. We had several varieties of shaded glasses and goggles, but found as much protection in the wooden shades made and worn by the natives as we did in our own improved glasses, and they were much more comfortable, as the moisture from the face did not congeal upon them so readily as upon the wire gauze and

does follo space thick dug sides cut it the cornw passes is see taker work snow camp lamp, that huts stood distriction distric

frames of the goggles. Other than this, there are but few hardships attending travel to a small party properly equipped in this region at this season of the year, and the nearer one conforms to the habits of the natives the less liable he is to meet with disaster, and the less he will be burdened with unnecessary camp equipage and blankets.

The snow but (iglu) of these people is very quickly and easily constructed, and ordinarily does not consume more time than is required to pitch a wall tent, and is constructed in the following manner: A place where the snow is about four feet deep is selected for camp and a space 5 by 9 feet is laid off; the upper surface is cut into blocks two feet square and eight inches thick and set on edge around the excavation for side walls; at one end three feet of the space is dug down to the ground or ice; in the balance about eighteen inches of snow is left for a couch; sides and ends are built up tight and the whole is roofed with broad slabs of snow six feet thick, cut in proper dimensions to form a flat gable roof, loose snow thrown over all to chink it, and at the end which is dug down to the ground a hole is now cut just large enough to admit a man crawling on his hands and knees; the hut is now finished, sleeping-bags, provisions, and lamp are passed inside, dogs are fed and turned loose after everything they would be liable to cat or destroy is secured by caching them in the dry snow. Arms, instruments, and ammunition should never be taken into the hut; it is always best to leave them on the sled in the open air. After all outside work is done everybody goes into the but and the hole is stopped from the inside with a plug of snow which has been carefully fitted, and no one is expected to go out until it is time to break camp the next morning. The combined heat from the bodies of the inmates, together with the lamp, soon raises the temperature up to the freezing point, and a degree of comfort is obtained that is not attainable in any other manner of camping in this region. The more permanent snow huts of the deer hunters, which they often occupy for a month or more, are much more elaborate. They are usually built where the snow is six or eight feet deep, so the room is high, and is approached by a covered way and an ante-room, in which the heavy outside clothing is stored, and when fuel is obtainable a kitchen is added to the structure, with a fire-place cut out of the sould walls of snow, with jambs and chimneys of the same perishable material. I saw fire places in use that had had a fire in them for at least one hour each day for a month or more and were still intact; the parts that were exposed had softened a little under the effects of the first fire and at once hardened into ice, and remained unchanged so long as the temperature in the open air remained below zero.

By the latter part of April or the first part of May snow houses are no longer tenable and natives take to their tents (túpēks). Their winter huts at this time are also vacated, as they become too damp for comfort. After the snow began to soften so it was no longer practicable to build a snow but I camped very comfortably by digging a hole in the snow 6 by 8 feet, building up side walls three to four feet high, and stretching over it a deer-skin blanket or the sled sail, using the sled mast for a ridge-pole and our showshoes for rafters. The natives in their excursions usually carry a small stone lamp and a supply of seal blubber for illuminating purposes; they use no blankets or sleeping bags when traveling, but earry a deer-skin or a piece of walrus hide to lay on the snow underneath them; on this they huddle together without any covering other than the clothing they travel in. \*\*t such times their food (meat or fish) is eaten raw, except where they have provides themselves with a kind of penmican, which is made by mixing chewed deer meat with deer tallow and seal oil. This food is not agreeable to the taste, probably owing to the fact that the masticators are inveterate tobacco chewers.

The sled we used on all our journeys was made by a native at Saint Michael's, and presented to the expedition by Sergeant Nelson when at Plover Bay; it was twelve feet long and twenty inches between the runners; had side rails, with a steering handle at the rear end, and was fastened throughout with rawhide lashings; the runners were shod with steel, and it was far superior to any sled I ever saw on the northern coast; it was still in excellent condition after two years' service; its carrying capacity was about 800 pounds, and I think it was the best pattern of a sled I ever saw for Arctic work; it was light (weighing only about fifty pounds), strong, and durable, and could always be repaired with the material at hand among the natives, should it at any time become damaged.

Early in May the hunters began to come in, and altogether I succeeded in gettir g from them eighteen deer, which together with five hundred eider-ducks killed by the party during the spring flight, gave us a large reserve supply of fresh meat, which was carefully stored in the cellar.

Sergeant: Mure och and Smith were indefatigable in their work, completing the collection so far as practicable in natural history, and many valuable specimens were obtained. Cracks opened in the ice to the north and west of the point, and whales were reported seen by the natives April 12; the leads were narrow, often closing entirely, with no water in sight for days, and the natives reported hearing or seeing whales nearly every day up to June 12.

The spring was very backward and we experienced a great deal of cold, disagreeable weather; the shore leads opened slowly. In Elson Bay and along shore to the eastward of Point Barrow the ice held on until late in August, and this prevented my getting along shore to the eastward with the whale-hoat before the arrival of the relief vessel, as I had intended. It was my desire to explore the coast as far as the boundary at least, and had the season been as favorable as that of 1882 I could have left the station by June 12.

On June 9 the natives succeeded in killing a large whale, the first they had taken since we had been on the coast, and was the cause of considerable excitement among them for several days; they came in from all points to join the general feast on the carcass, which was free to all who cared to come and partake.

By the first of August we were becoming extremely anxious about a vessel reaching us this season, as the ground ice was still intact from Point Barrow to the Sea Horse Islands, and it was impracticable to work a small boat along shore. The whale-boat was fitted and provisioned for a voyage and held in readiness for a move as soon as the ice would let us out; outside the bar there was one narrow open lead extending as far as the eye could reach to the southwest, but there was no break in the ground ice to let us into it; besides, it closed under a westerly wind or when the prevailing northeast wind slacked up. On the morning of August 1 a thick fog hung over the ocean, and when it lifted, about 7 o'clock, our eyes were gladdened by the sight of three steamers six miles away, working slowly up the lead from the southwest. With Captain Herendeen I at once crossed the ground ice and went on board the nearest ship, reaching her about 11 a. m. Found it to be the Orca, Captain Colson, from San Francisco, a new vessel on her first voyage. From her we received our first mail, and from private letters learned that the station was to be abandoned as soon as a vessel could reach us. Captain Colson reported the balance of the whaling fleet lying at anchor along the coast between Point Hope and Cape Belcher; not being so well fitted as the new vessels, they would not venture into the pack. The Orca tied up to the ground floe off the station until along in the afternoon, when, in company with the Bowhead, Balæna, and Narwhal (all steamers that had now come up), she proceeded on up to the Point; the lead here was closed and the pack was solid to the north and east, and fast on the land to the eastward of Point Barrow; they tied up under the lee of a large floe berg that had grounded in four fathoms of water.

The following day the steamers Belvidere, Lucretia, and Mary and Helen, came up bringing considerable mail, but no orders, except one from the Chief Signal Officer directing me to dispose of such stores as could be sold to advantage. I sold what I could to the fleet, packed everything not required for immediate use, and as far as possible, without discontinuing the work of observation, made everything ready to embark, so that when the vessel sent to our relief should arrive she would be delayed as short a time as possible.

By August 15 several sailing-vessels had worked up to the station, and all were at anchor behind the ground ice which had now broken away in several places; there was also an open lead along shore. On the 16th the bark Sea Breeze (Captain McDonald) anchored off the station and reported that he had spoken the schooner Leo at anchor off Point Belcher, eighty or ninety miles to the southwest, with orders for the station. He also reported the ice close in off Sea Horse Islands, and that he thought the master of the Leo did not care to venture into the ice, as he had been lying there over a week. I at once prepared to go to her in the whale-boat by working along shore, but a heavy gale springing up from the northeast on the 17th prevented our sailing. In the mean time Capt. L. C. Owen, of the bark Rainbow (who was master of the North Star when she was wrecked in 1882), came to the station and tendered me the services of his steam whale-boat for the trip, which was very gratefully accepted. He sent it down to me on the 19th, with Mr. Rogers, his first mate, in charge, and a crew of three men. I left the station at 6.40 p. m. the same day, with Sergeant Murdoch and Interpreter Herendeen. The weather was clear and warm,

with little or no wind when we started, so we steamed along shore about one-fourth mile from it, keeping inside the ground ice. At 8 p. m. a strong breeze came out from the northeast, when all sail was set, and we made great speed, so that by midnight we were off Sca Horse Islands; by this time there was a heavy sea running, and the wind had increased to a gale, and we were running before it under clove-rected mainsail and all steam, to avoid being pooped and swamped, as the sea was breaking heavily on the shoals off Point Franklin. The heavy pack was aground on the outer bar, but there was room for a vessel to pass between it and the shoals.

After rounding Peart Franklin we headed for Point Belcher, and at 2 a. m. sighted several vessels at anchor off the point, apparently making very bad weather of it, as there was no shelter here from the wind and sea. As we neared them we were able in the dim twilight to make out the Leo by her peculiar rig, she being a topsail schooner, and we here up to her and succeeded in getting a line on board as we swept past, and with considerable difficulty were taken on board. The gale increased in fury, and before we could hoist in the launch the Leo dragged her anchor and drifted rapidly to the leeward. The captain ordered the cable to be slipped, and the vessel got under way, and I requested him to keep her on a northwest course until he came up with the ice. While the vessel was being got under way, Mr. Rogers, who saw his launch was in danger of being swamped, sprang into her with his crew, cut the painter, and they disappeared from our sight in the storm. We were extremely anxious for his safety, and we had seen that all of the whalers had been obliged to put to sea at the same time we did, and that it would be impossible for him to land north of Wainwright's Inlet without losing the boat, and it was doubtful if he could keep her afloat until he reached that point. At 4 a. m. we came up with the main pack, and the vessel was hove to under the lee of a large field of ice that seemed to be nearly stationary. Here she safely rode out the gale, which abated during the night, so that on the morning of the 21st we were able to stand in toward the land, which we sighted at 7 a. m., and stood in in search of the launch and the anchor which had been slipped and buoyed the day before. At 10 a. m. the captain recovered his anchor, and we stood to the southwest along share in search of the lannch, but were unable to find any trace of her that day.

The next morning, when off Wainright's Inlet, we spoke the bark Helen Mar, and found she had the boat and party safe on board, having picked them up that morning. We then learned that Mr. Rogers had succeeded in making Wainright's Inlet after he went adrift from the Leo. and had ridden out the gale at anchor there, and, sighting the Helen Mar before he did the Leo. had gone on board of her. The wind being southwest, strong and favorable, I directed Captain Jacobson to put the Leo on her course for Uglaamie, which he did, and we came to anchorage of the station at 7 p. m., on the 22d, passing through and past considerable pack on our way. I at once landed Mr. Marr, an assistant of the United States Coast and Geodetic Survey who had been sent up to make a series of pendulum observations, with a part of his instruments; gave them all the assistance I could. At the same time I pushed the preparations for embarking, as the ice was liable to close in at any moment. We suspended work at 10 p. m. It came on to blow heavily from the southwest during the night, sending the pack in. The Leo slipped her sable, and escaped around the Point to avoid being crushed or forced ashore. We could see her spars above the ice to the eastward of the Point when we got out in the morning. Private Clarke, of the Signal Corps, and Mr. Schindler (Mr. Marr's assistant), who remained on the Leo, came down to the station overland during the day, and reported the Leo uninjured. During the aight of the 23d the wind came out from the northeast and blew heavily, setting the ice about one and onehalf miles off the western shore, allowing the Leo to work around to the westward of the Point during the following day, where she came to anchor at 10 p. m., the wind being too light for her to stem the strong northeast current that was setting along the shore. The wind hauled to the southeast and freshered during the night of the 24th, so that she was enabled to get under way and reach the station, anchoring there at 7 a.m. I at once caused the balance of Mr. Marr's instruments and material to be landed, but was unable to embark any stores, as Captain Jacobson in his efforts to recover his cable and anchor which he had slipped on the 23d, had gotten so far off shore that we were unable to run a line to the vessel for the purpose of warping our boats to and fro. This was necessary, as I had not sufficient men to fully man the boats and handle the stores, and the natives' boats could not be with safety used in the sharp ice that was running

with the coeffit and piled high on the beach. We worked all day trying to kedge the schoener in, but the wind blowing a gale off-shore rendered all our efforts futile. I placed Interpreter Herendeen on board that night, so that Captain Jacobson could have the benefit of his experience and advice should she again be driven away from her anchorage, as Captain Jacobson was totally inexperienced in Arctic navigation.

Just before dark five whaling barks came around the Point and anchored one and a half miles above the station. We all spent an anxious night for, the wind increased to a gale and hauled to the southwest and we could hear in the darkness the grinding of the pack as it came in, and were not surprised in getting up the next morning to find that the Leo was gone again, and that the sea was closed as far as the eye could reach. The Leo had escaped again around the Point, but three of the whaling barks had not been so fortunate; they were all fast in the pack, the crews were passing and repassing from the ship to the land over the ice. Two of the vessels had gotter foul of each other, and one, the Abraham Barker, had lost her rudder. With a glass from the lookout we could make out the Leo to the eastward of the Point, looking like a speek among the great ice fields. During the day the gale abated, the pressure slackened up, and toward night several small leads were visible. The wind came out from the southeast during the night, and early the next morning the Leo was seen to be under way slowly working her way back to the station through a narrow shore lead that opened during the night; she came to anchor off the station two hundred yards from the beach. Upon going on board I found her considerably damaged; she had been nipped, her stem partly knocked off, her rudder post split, and she was leaking badly.

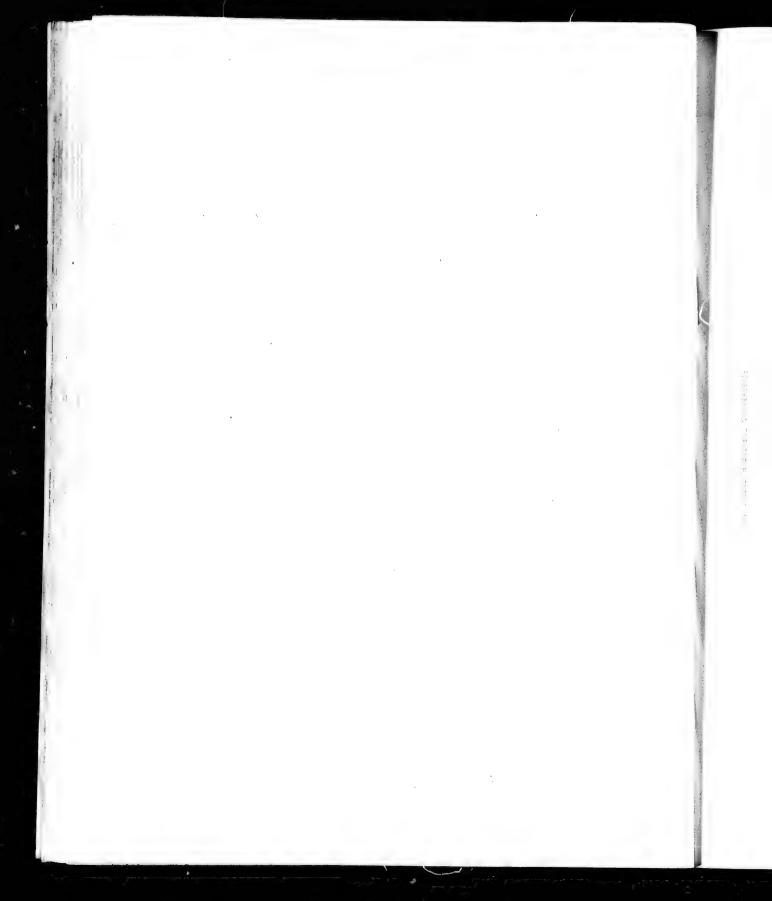

In view of these facts, and orders having been received for the return of the party to the United States, I determined to abandon the station at once. During the past two days I had caused all the subsistence and quartermaster stores worth saving to be carried down from the house to the beach; a whale-line was run from the shore to the vessel, so one man could had the boats to and fro, and the embarking was commenced at once, the first boat-load going on board at 8 a. m. Mr. Marr discontinued work on the pendulum, and took down the parts he had placed; the work went on rapidly with the two whale-boats belonging to the station. It was still impossible to use the native boats with safety, as there were great masses of loose pack-ice running with the current, and the beach was piled high with broken ice; at 2 a. m. the instruments were taken down and packed, and observations on shore ceased; the last boat-load was sent off at 10 p. m., and at 12 midnight the party went on board, leaving one man on shore, to see that the natives did not carry off anything

that might have been accidentally left.

The ice was too heavy and compact the next morning to enable us to get under way, so the captain improved the time in grappling for the anchor and cable he had slipped the night of the 25th; he succeeded in recovering it, which was extremely fortunate for it was his best, the remaining one being very light. I took a party on shore and brought off the few remaining articles of any value that I did not intend to give to the native;. I left them the house and furniture intact with the stoves, and about 12 tons of coal, a grindstone, some old canvas, and a few worn-out tools, were about all that was left; but these were of great value to the natives, and after giving them a feast of hard bread and molasses we bade them good bye, amid many expressions of regret at our departure. I placed the buildings in charge of some of the most influential men, who promised they would not allow them to be torn to pieces, but be kept as a place of refuge for any shipwrecked people who may chance to be cast ashore on this barren coast. A whale-boat passed up during the day with Captain McKenna, of the bark Cyanne. He reported that his vessel was driven ashore off Point Belcher, in the gale of the 25th, and would prove a total loss. He came up to get assistance from vessels at the Point in saving her valuable cargo of whalebone.

On the morning of the 29th, the lead to the southwest being open and the wind being favorable, the captain took his anchor and got under way at 6 a.m., and we commenced our honeward voyage. The familiar shore and village and the house that had been so good and comfortable a home to us for two long years soon faded in the distance. After sailing two miles we got clear off the loose ice that was running with the current and into clear water, with the old pack close in to the northwest, arriving off Point Franklin at 9.30 p. m., when the wind fell, and we came to anchor in company with cleven ships of the whaling fleet that had worked out and had come down

the same time we did. The wind came out from the westward during the night, and the captain got under way; stood off and came up with the pack about six miles from the land, when he tacked and stood in towards land; but again the current was setting so strong to the northeast that we could not make any headway on our course, and we were very glad to get back to our our anchorage under the lee of Point Franklin, where we lay until the next day, when we again got under wry with a light southeast breeze, which let go after we had gotten around the Point, and we were again obliged to anchor at 10 a.m., to prevent being carried off to the northeast by the strong current setting along shore here.

Sailing-vessels navigating this sea should never allow themselves to get off soundings north of Point Belcher, except in a strong, steady wind, nor allow the vessel to drift during thick, calm weather, if i\* is possible to get an anchor down. The needle is useless here; the land or lead line is the only safe guide, for, should a sailing-vessel be carried off soundings off Point Barrow with light wings or calm, she runs gree\* danger of being lost; this has been the fate of nearly all

vessels so caught, especially late in the season.

At 4 p. m., the breeze freshening, we got under way again and stood on our course along the coast and about four miles from it. We experienced light, baffling winds, making but little headway from that time until the afternoon of September 2, when the wind came out strong and steady from the northeast. We sighted and passed Cape Lisburne that day and sighted the Diomede Islands at noon on the 3d. During the day the wind increased to a gale and the weather grew thick and cold, with considerable snow; sail was shortened, and at 3 p. m. we passed Cape Prince of Wales, running at great speed before the wind; after passing through the straits the vessel was headed for Norton Sound, it being necessary that I should go to Saint Michael's to land Private E. Clarke, of the Signal Corps, who had been sent out to relieve Sergeant Leavitt, an observer on that station. As soon as we hauled under the high land to the south and east of Cape Prince of Wales we ran out of the wind, and our progress was slow.

On the 4th of September the fog lifted and we sighted Kings Island and Cape York, and on the 6th passed close to the southward of Sledge Island, but, owing to a head wind, did not sight the high land near Saint Michael's until the 8th. We stood in towards it and came to anchor off the fort at noon on that day, where we were received by a salute fired from a couple of old ship guns. Soon after a boat came off to us bringing, very much to our surprise, Lieut. Frederick Schwatka. Third Cavalry, who reported that he had made the passage of the Yukon on a raft, exploring its course from its source to its mouth, making one of the most remarkable raft voyages on record. He had been at Saint Michael's since the last of August, and was extremely anxious to get away with his party. Though we were very much crowded on the Leo I did not think it would be right to refuse him passage, as there would be no opportunity for him to return to the United States before another year, this station being visited only by vessels of the Alaska Commercial Company, and there would be none due before the following June. So I directed him to hold his party in readiness to come on board as soon as we were ready to sail. We were short of fresh water and had to lay in a supply before again putting to sea. For the first two days we were in port it blew a gale from the southeast, so it was impossible to get any water off to the ship; on the afternoon of the 16th the captain reported he had succeeded in getting enough on board to last us until we could reach Unalaska or Plover Bay, whichever place I should conclude to go to, so at daylight on the 11th Lieutenant Schwatka and his party were taken on board and we put to sea at 10 a.m. Found it was blowing a gale from the northwest when we got outside, and after making a few tacks under close-reefed sails, found we were making no headway, so we were glad to run back into the harbor, where we came to anchor at 3 p. m.

The following morning, the wind having hauled more to the north, we again put to sea, and the next morning sighted Cape Darby, a high headland on the northern shore of Norton Sound. We were obliged to make this northing to avoid a dangerous shoal that makes out from the mouth of the Yukon; in running out of Norton Sound it is not safe to run west, south of 64 Lat. During the afternoon of the 13th the wind settled in the northwest and blew hard and steadily all that night, and we found it would be slow work beating up to Plover Bay. The ship was leaking so badly that the pumps were kept going one-third of the time and the slightest accident to them would soon send her to the bottom; and as I knew that the meridian of Unalaska had been as well,

if not better, determined than that of Plover Bay, I decided not to go to the latter place, but to proceed direct to Unalaska and there make an effort to repair the vessel, as I was told that there was sufficient tide at that place to enable us to get at her bottom by discharging her cargo and placing her on the beach at high tide and working on her during low water; so as soon as we were clear of the Yukon fatts she was put on her course for that place. The wind increased to a heavy gale from the northwest on the 15th, and we made excellent time as we were running nearly before it. During the night of the 16th, the vessel was hove to to wait for daylight, as we knew we were near land, and on the morning of the 17th we sighted the island of Unalaska to the south and about twenty miles away; the wind had fallen so light during the night we were able to make but little headway and did not get into the barbor and at anchor until 10 o'clock that night.

We found the United States steamer Corwin and the Alaska Commercial Company's steamer Dora at anchor here, the former on her return from Kotzebue Sound and the latter on her annual voyage to the Aleutian Island stations. The wind not being favorable to sail into the inner harbor, which was the only place where the vessel could be safely beached, I made application to Captam Healy, commanding the Corwin, for the assistance of the cutter to tow the Leo in . he very readily complied with the request, and at once got up steam, and at 11 a. m. placed the Leo at the company's wharf, where the bulk of her cargo was discharged; owing to a severe wind storm prevailing at this time we were unable to haul her up until the afternoon of the 20th, when she was beached at high tide; we improved the time in getting observations of the sun, and determining the declination of the needle. We were unable to get at the leak on the first ebb, but on the 21st the water fell sufficiently low to enable the workmen to repair the damage, which was found to be about four feet below her water line, where a butt had been started, and the water was so clear that we could see that she had sustained no damage below that point, and we were pleased to find upon floating her off on the next high tide that the leak was entirely stopped.

Such stores as had not been disposed of were re-embarked on the 22d and the vessel warped out to her anchorage ready for sailing. The 23d was too stormy to admit of our going to sea, but the wind having abated slightly toward night, I directed the captain to get under way on the morning of the 24th, which was done at 8 a. m., being towed outside the heads by the Corwin, whose services had again been kindly placed at our disposal by Captain Healy. We found the wind blowing strong from the northwest when we got outside, and a very heavy sea running: we parted company with the Corwin as soon as we passed the capes by the breaking of our tow-line, and the Leo was at once headed for the pass of Akontan, through which we passed out into the Pacific at 12 m. From this time the wind continued fair during the whole of the voyage across the North Pacific. We followed nearly in the track of the great circle route, and made such

ETI

remarkably good time that the Farallones were sighted at 3 p. m.

On October 6 the wind fell as we ran in toward land, and we drifted through the Golden Gate in a dead calm that night at 12 o'clock, coming to anchor off the Presidio at 2 a. m. October 7, and

reporting to the Chief Signal Officer by telegraph the same day.

The object for which the expedition was organized being accomplished, it was formally disbanded October 15; its work having extended through a period of over twenty-seven months, during which time the expedition had sailed over 7,500 wiles, had established and maintained itself at the northern extremity of this continent in latitude 71° 16' north, and successfully carried out the instructions received from the Chief Signa! Officer, and brought back the record of an unbroken series of hourly observations in meteorology, magnetism, tides, and earth temperatures, besides a large collection in natural history and ethnology, and penetrated into the interior to a point never before visited by civilized man.

During the whole period all the members of the expedition enjoyed excellent health, not having

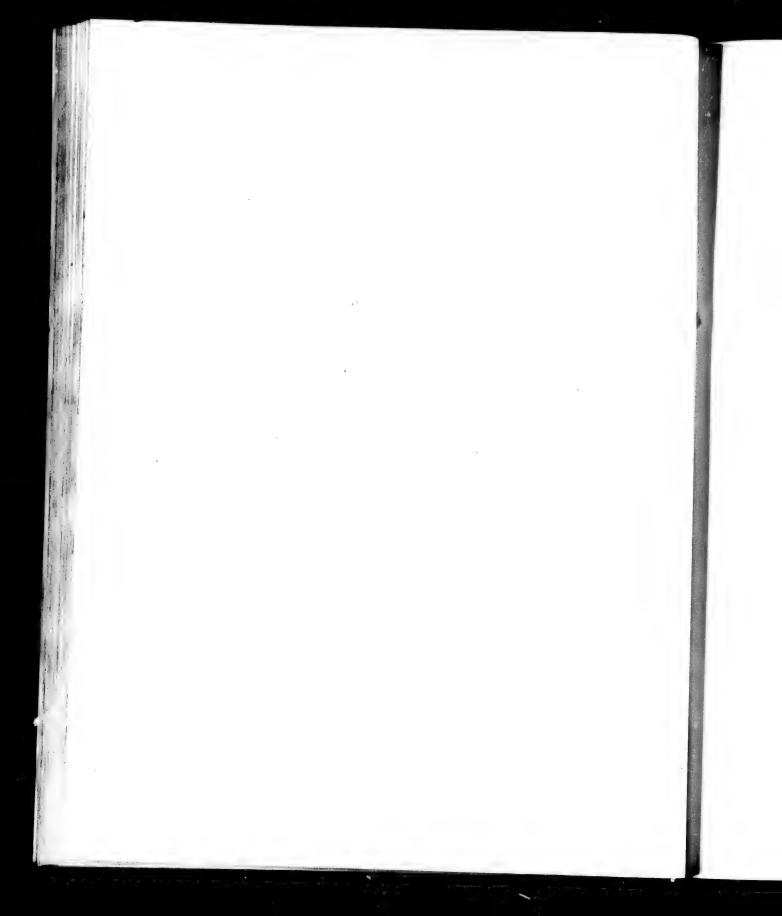

a single man on the sick report for two years.

To the individual members of the expedition who returned with it to the United States great credit is due for their obedience to orders, faithfulness, and intelligence in performance of their duties, and for their patient endurance of the many trials they were called upon to suffer; for the work of scientific observations in these high latitudes is one of patient endurance on the part of the observer, confined, as he is, within narrow limits, without the excitement incident to travel. The unvaying monotony of the work is necessarily very wearing, but during the whole time no murnaur or complaint was ever heard.

## ETHNOGRAPHIC SKETCH OF THE NATIVES.

I.

During our stay we improved each opportunity to add to our knowledge of the peculiar people inhabiting this coast. A want of sufficient knowledge of their language at first made the work difficult, as we had no interpreter. So our first energies were devoted to learning their language sufficiently well to communicate with them, as none of them could speak a word of English relater did they show any disposition to learn.

Of their origin and descent we could get no trace, there being no record of events kept among them. Even the sign record of prominent events in individual life, so common among some of the natives in the lower latitudes, is almost unknown among them. Their language abounds in legends, but none of these gave any data by which we could judge how long these desolate shores have been inhabited.

That the ancestors of those people have made it their home for ages is conclusively shown by the ruins of ancient villages and winter huts along the sea-shore and in the interior. On the point where the station was established were mounds marking the site of three huts dating back to the time when they had no iron and men "talked like dogs"; also at Pevigniak a group of mounds mark the site of an ancient village. It stands in the midst of a marsh; a sinking of the land causing it to be flooded and consequently abandoned, as it is their custom to select the high and dry points of land along the sea-shore for their permanent villages. The fact of our finding a pair of wooden goggles twenty-six feet below the surface of the earth, in the shaft sunk for earth temperatures, points conclusively to the great lapse of time since these shores were first peopled by the race of man. That they have followed the receding line of ice, which at one time capped the northern part of this continent, along the easiest lines of travel is shown in the general distribution of a similar people, speaking a similar tongue, from Greenland to Behring Straits; in so doing they followed the easiest natural lines of travel along the water-courses and the seashore, and the distribution of the race to-day marks the routes traveled. The sea-shore led them along the Labrador and Greenland coasts; Hudson's Bay and its tributary waters carried its quota towards Boothia Land; helped by Back's Great Fish River, the Mackenzie carried them to the northwestern coast; and down the Yukon they came to people the shores of Norton Sound and along the coast to Cape Prince of Wales. They occupied some of the coast to the south of the mouth of the Yukon, and a few drifted across Behring Straits on the ice, and their natural traits are still in marked contrast with their neighbors, the Chuckchee. They use dogs instead of deer, the natives of North America having never domesticated the reindeer, take their living from the sea, and speak a different tongue. Had the the migration come from Asia it does not stand to reason that they would have abandoned the deer upon crossing the straits.

The following table will show that physically the Inyu of North America coast does not conform to the typical idea of the Eskimo. They are robust, healthy people, fairer than the North American Indian, with brown eyes and straight black hair. The men are beardless until they attain the age of from twenty to twenty-five years, and even then it is very light and scattering, and is always clipped close in the winter; at this season they also cut off their eyebrows and tonsure their crown like a priest, with bangs over their forchead. Their hands and feet are

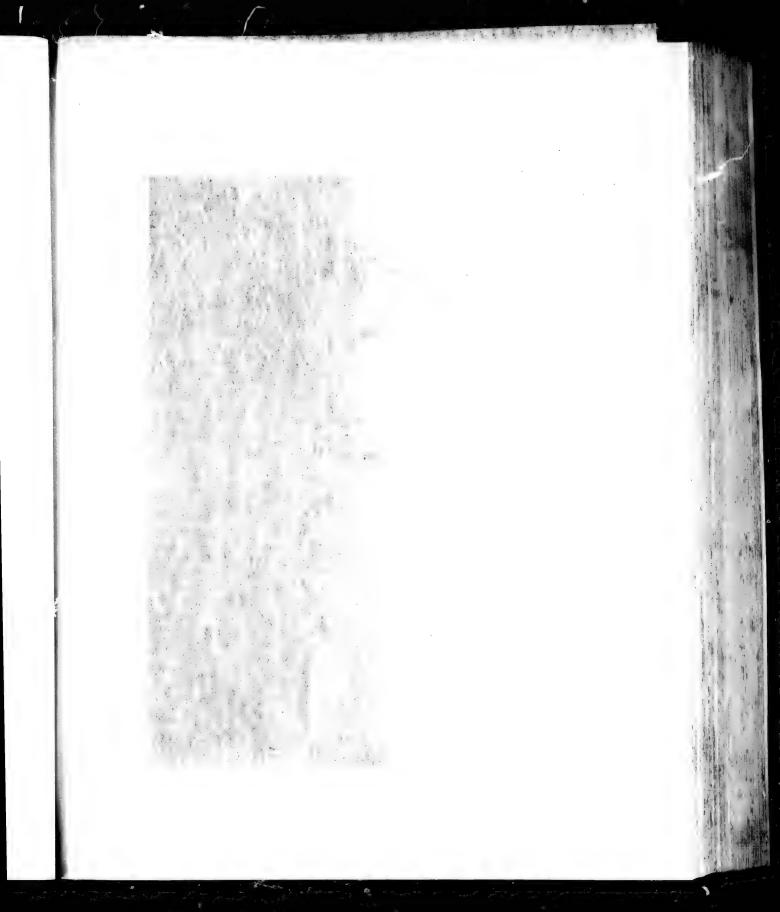

extremely small and symmetrical; they are graceful in their movements when unincumbered by heavy clothing; they are kind and gentle in disposition and extremely hospitable to strangers; though they may rob a stranger of every means of obtaining a subsistence one moment, they will divide with him their last piece of meat the next. They have no form of government, but live in a condition of anarchy; they make no combinations, either for offensive or defensive purposes, having no common enemies to guard against, nor have they any punishment for crimes. I never knew one to attempt to reclaim stolen property, though they might see it in the hands of the thief or left on his cache; though given to petty pilfering they rarely, if ever, break into a cache (except into one of meat when driven to it by hunger) or enter a tent or but for that purpose, During the first winter we had stores, of which they were in great need, in a Sibley tent, and they all knew they were there; and although the tent was only tied, with no regular guard over it, nothing was ever disturbed, though if anything was carelessly left out it would be stolen at once. They never made the slightest resistance to our reclaiming property when discovered, and would laugh about it as though it were a good joke. They are very social in their habits and kind to each other; we never witnessed a quarrel between men during the whole time we were on the coast, neither did we ever see a child struck or punished; and a more obedient or better lot of children cannot be found in all Christendom. I never saw one of any age do a vicious or mean act, and while they were always around the station during the fall and winter, they did no mischief, but, on the contrary, would busy themselves in shoveling the snow out of the tunnels and running on errands and doing any work they could for a little food each day. The children would wait around the door for members of the party to come out to take their daily exercise, and, even more, would accompany each member, and every few moments they would say "naumi-tanity" (now let me see), and would scan the traveler's face for frost-bites, and were ever ready with a handful of snow to be applied should they detect the slightest sign of freezing; for when the temperature gets below  $-45^{\circ}$ , and there is a light breeze, it cuts every exposed part of the body as though white hot metal were applied, causing no pain. Their games were very alike what we see played among children of our own race, and in imitating the pursuits of the elders, we often saw them with snow play-houses cut into the hard snow, with snow images set up, and the little fur-clad mites of humanity bustling around, playing at keeping house and making calls, with the temperature at  $-40^{\circ}$ .

All the people on that coast from Wainwright Inlet around to the mouth of the Colville are comprised in the following villages whose population comprise all the inhabitants of this coast:

Name of village,	Location.		Total population.
Kunmenm	Wainwright Inlet	10	80
Sidára	Southwest Point Belcher	8	50
Ŭglaamie	Cape Smythe	23	130
Nuwak	Point Barrow.	31	150
Total			. 410

Between Point Barrow and the Colville the country is uninhabited in the winter. The resources of this region are so limited that in the struggle for existence, these people are obliged to devote all their energies and time to procuring necessary food and clothing to maintain life, never being able to get a sufficient supply of meat ahead to lay in a reserve; famine always stares them in the face should they relax their efforts.

With the return of the sun each year their active life commences. These that have arms and dogs go into the interior about the 1st of February to hunt reindeer; those belonging to the villages of Nuwük and Uglaamie go to the south and hunt along the Meade and Ik-pik-piū; those from the vicinity of Wainwright Inlet hunt along the Ku; the others scatter along the western shore for the purpose of taking seal, and ducks as the season advances. Their tents, one or two in a place, seen by summer voyagers in this sea, has given rise to the belief that this coast is much more densely populated than it is in fact. For when the tents are out the villages are empty.

bo th (in tire Co tue be

The hunters return to the winter huts between the 1st and 10th of May, and the omeliks or boat-headers make up their crews for the whaling season. A boat-header (omélik) is one who is noted for his success in taking whales, and of course is a man of experience and considerable influence. The crews are made up of men and women, generally ten to each boat; some crews are paid by the omelik, who feeds them and pays them in deer skins or other articles of native traffic; others ship on a lay, each member furnishing his own supplies and they all share alike in the catch, the boat-header furnishing the gear. The women who are tabooed and the children cook and carry food out to the crews, who come in to the land as seldom as possible, and never go into a house, if it can be avoided. At this season, too, no work is done that will necessitate pounding or hewing or in fact any noise, neither shall there be work of any kind carried on in the tent (tupek) of any member of a crew. Should their garments be accidentally torn, the woman must take them far back on the tundra out of sight of the sea and mend them; they have little tents, in which just one person can sit, in which this work is done. During the spring of 1882 they came to me and asked that I stop the work on the shaft, saying that it would offend the whales at this season. Early in March all hands turn to and build a road through the pack over which the boats can be hauled out to the lead; this often necessitates a great deal of labor, especially when the lead opens far off shore, as it did in 1882.

The village and camps are in a constant state of bustle and excitement at this season of the year; boat covers are being renewed or repaired; harpoons and lances are gotten out and every part of the woodwork carefully scraped; seal-skin pokes are lying about, looking like bloated seals, and the skulls of wolves, raven skins, or eagle skins are in great demand, for no no boat would be considered equipped without some such talisman. Daily the old men, especially those who are successful in curing the sick, meet on the sea-shore and (abawa) talk for an east wind, so the ice will be driven off shore and a lead, favorable for whales, opened; and their faith remains unshaken through repeated failures, and when questioned as to the reason why their supplications remained unanswered they always attributed it to some offense they had given to the spirit. When the lead opens there is great rejoicing, and for a few days they display the utmost vigilance; but should the whales fail to appear in a few days, they soon grow careless and cease ernising, haul their boats up on the ice and patiently wait for a whale to come to them, taking turns in standing watch while the others sleep or shoot seal and duck, which abound in the open leads at this season.

As the season advances the boat crews are gradually broken up, and by the middle of June all boats are brought to the land, when parties are made up to go to Nigalèk, a place at the month of the Colville, where the people from Nuwik and Uglaamie go to meet a band called Nn-na-tá/ñ-meun (inland people), where they barter oil and blubber for deer, fox, and wolverine skins. They sometimes meet here the Kûñ-mû/d²-lûs and It-kû/d¹-lûs, bands that live along the coast between the Colville and Mackenzie. This meeting breaks up about the 15th of August, when they slowly return along the coast, hunting by the way, and reach their winter villages from the 15th of September to the 1st of October, about the same time the traders go to the eastward.

A few of the leading families from both villages pitch their tents at Perigniak, a point on the sand spit, about five miles from Nuwük, where the eider ducks fly over, and spend the summer there, living entirely upon ducks and whitefish. The ducks they take with slings and guns and the fish with gill-nets made from sinews of the reindeer. Those who are too poor to own a gun or to have oil for trade scatter through the interior, carrying their kaiaks on their heads to cross the numerous lakes and river's, and gain a precarious livelihood by catching the young reindeer, the young and moulting ducks which are found in great numbers in the lakes and along Meade River, where they also take a few whitefish with gill-nets. The ducks are taken with a light ivory-headed spear, which has a shaft seven feet long, one-half inch in diameter, with three long ivory barbs in the middle. It is thrown with a hand-board from a kaiak, the barbs catching the birds by the neck when missed by the lariat stroke.

Their usual mode of travel along the shore in summer is by the umiak, the large skin boat; with a fair wind they hoist a small lug sail, but the boats being flat bottom will not sail on the wind, so with a head wind or calm weather the boats are towed by dogs, using the walrus harpoon line for a towing line; they never resort to the labor of paddling except when in pressuit of game or in

some emergency. When a landing is made the boat is hauled up above high water, and turned over and serves temporarily for a tent. By the 1st of Oetober all have returned to their winter huts, and are busy getting them in order for the winter; all the inside timbers and floors are carefully scraped, the passages which have become filled with ice during the summer are picked out, windows of walrus intestines are stretched over the openings, and by the 15th all are housed for the winter. And the seal-nets and spears are repaired and made ready, and, as soon as the ocean is frozen over, parties are constantly out on the ice, hunting for air-holes where the seal come to get air. As soon as one is discovered a number of families go off to it in the following manner: the nets are twenty-five feet long and fourteen feet deep, with meshes large enough to admit a seal's head, and are rigged with stone sinkers along the bottom, and at the two upper corners are attached two rawhide thongs ... out for a set long, one of which has a light weight attached to the end. Holes twelve inches in dia... the ice about sixty feet ted fine is dropped through one hole, and hauled up through the back from the air-hole. other by a long pole with a book attached; this pole is made from small pieces of drift-wood carefully spliced together with lashings of whalebone; by this line the net is hauled underneath the ice, hanging down like a curtain between one of the holes and held in its place by the lines being attached to a wooden pin. In this manner the air-hole is surrounded by nets as far as practicable; one man or boy is left to attend to each net, and the strictest silence enjoined; no word is spoken; the watcher, wrapped in his heaviest coat, patiently awaits through the long hours; he occasionally scratches the surface of the ice with a scratcher, which is made of a set of seal claws attached to a piece of wood. The seal, in coming to the hole for air, strikes into the net; the strain loosens the lines from the peg and he entangles himself and soon drowns, when he is hauled out through one of the sealing holes and the net reset. Over one hundred seal are sometimes taken at a single air hole within twenty four hours, but they can be taken in this manner only during the dark of the moon—any light will betray the presence of the net. During May quite a number are taken at their breathing-holes, which have become enlarged, and through which they haul out on the surface of the ice at that season, by removing the weights from the nets and setting it across the hole with four lines on the under side of the ice.

At this season, also, many seals are taken with the hand spear, at the "adlu," the breathing-hole of a single seal. It is usually detected by an excessive deposit of hoar-frost on the surface of the snow over the hole; the snow is cleared away down to the solid ice, and in the hole, which is about one inch in diameter at the surface, is placed an ivory needle about one foot long and one eighth of an inch in diameter; to the upper end a small cross-bar is attached, to prevent it dropping through, and a small feather, and the hunter takes his stand on a three-legged stool, which is always a part of his regular equipment, and patiently awaits the coming of the seal, of which the feathered needle gives warning; after the stroke is delivered, if he succeeds in fastening to the seal, he proceeds to cularge the hole until it will admit hauling him to the surface; this is usually done with an ivory pick attached to the shaft of his spear; as soon as a seal is taken its mouth is fastened open with a piece of ice, and a slot cut through the lower jaw before it becomes frozen. Should be be far out in the pack, where the ice is too rough for a sled to be used, the seal is dragged home by a hand drag, which is a strong loop about two feet long, made of walrus hide thong, fitted with an ivory toggle or handle, generally carved in imitation of two seals fastened together; this loop is passed through the slot in the seal's jaw and over the toggle; each hunter must be supplied with at least one of these drags, as it is not considered proper to fasten to a seal with a line that is used for any other purpose; when they get near shore the drag is removed and a few drops of fresh water is poured into the mouth of each seal before it is taken from the ice to the land; they generally go through with the same ceremony with ducks that have been killed at sea, but never with those that have been killed over the land, and the bones of seals are carefully preserved unbroken and returned to the sea, if possible, either by being left in a crack in the ice, far out from the land, or dropped through some open hole in the ice. By so doing they believe that good fortune will follow them in pursuit of seal, which is their main dependence, for from its skin they make their summer boots and soles for their winter boots; its blubber supplies the oil for their lamps during the long night, and with any surplus they may have they purchase deer-skins for clothing from the natives from the interior, and its flesh when cooked is an excellent article of food. The few

walls were acros in fre reindeer and water fowl they take are looked upon more as a luxury than a necessity, and the flesh of the reindeer is the greatest luxury of all; those who have it careful: Fourd it, and when they knew that we had some in store they would often come and beg for a small piece to be used as medicine for some sick person.

Immediately after the departure of the sun, when food is plentiful, it is asstomary for each village to hold a kind of high carnival for three days; friends are invited from the neighboring villages, and the time is passed in dancing, singing, and feasting; the "kûdyigin" (council-house) is fitted up with a new roof of ice, and crowded day and night, fresh dancers taking the places of those tired out, and the dull tum-tum of the drum, mingled with snatches of song and shouts of laughter can be heard coming from almost every iglu.

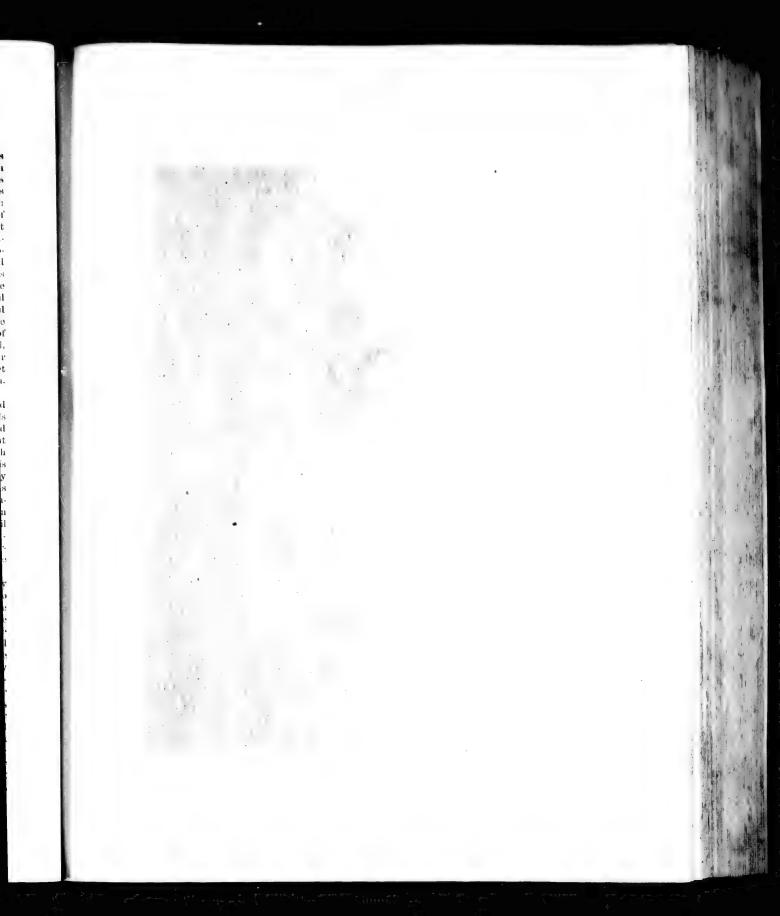

It is customary at this season to exchange presents, especially among the more wealthy and influential ones; but the giver expects value received in return, and should be fail to receive a satisfactory present he does not fail to let his wants be known, and he often announces beforehand what articles would be most desirable in case he should make a present. In 1883 I was invited to attend one of these gatherings at Numuk, and the old omelik who was sent as bearer of the invitation brought a statement of what they were going to give me; after waiting around the station for an hour or two he called me to one sale as called over a long list of articles that they expected me to give in return, but as rum (tût $\tilde{r}$   $\sim$ ), rific  $\sim$  and ammunition were leading items in the list, the visit was never made. A trade is made a matter of grave debate, and frequent discussions asking for a little more, no matter how much has been offered, and when an offer has been made they will go away and send the article by another person; and often when a trade has been completed they will come and demand their goods back, often leaving the articles they had received on the door-step, and when asked what tive will take have great difficulty in making up their minds; and in making boots and clothing they will slight their work in every imaginable way unless carefully watched. I had occasion to purchase seal-oil, and they commenced bringing it to me in old tin cans that they had picked up at the station, and after a few honest deliveries they commenced bringing us cans filled with two-thirds ice and a little oil on top, and betrayed themselves by being over-anxious to get their pay before we emptied the cans.

My first invitation to one of their ceremonies came in December, 1881, through old Nikawaalu, of Uglaamie, who came over to the station with a small delegation and in a grave, dignified manner said that the people of Uglaamie would be made glad if Captain Herendeen and myself would come with him and see the dance. We at once started over, and as we approached the village we found a crowd upwards of 200 people collected around the council house; besides the Uglaamie people, there were delegations from Nuwuk and Sidaru. They were silently watching a pantomime that was being enacted by five men and two women who were standing in a row with the women on the right and left, facing the south, with the council-house behind them, and the crowd in front. They were attired in new suits of deer-skin worn with the flesh side out, dressed perfectly white; the men were tall conical hats of seal-skin, ornamented with dentalium shells and tufts of ermine and Arctic fox fur. The women were bareheaded, with their hair neatly plaited. Behind the dancers sat a drummer and two singers, to whose doleful chant the dancers kept time with their feet, at the same time swaying their bodies from right to left with spasmodic jerks, the women occasionally joining in the song, while the men one at a time would spring a few paces to the front and in wild gestures portray how they had taken seal, bear, or deer, being cheered by the crowd as they finished and took their place in the line. The day was clear, and their grotesque figures showed in sharp relief against the southern sky that glowed with the twilight of a winter noon; their wild surroundings, backed by a frozen ocean, made up a picture peculiar only to the Arctic, and, once seen, not soon to be forgotten. After each had danced in turn, and it seemed a long time to us standing waiting in the snow in a temperature of 18°, they adjourned to the council-house, where as many crowded in as could find standing room, in a room 16 by 20; the air was redolent with odors from the lamp and the unwashed crowd, and, as the frost had hermetically sealed the roof and walls, there was no ventilation and the heat and stench soon became almost unbearable to us who were unaccustomed to such life. Two large stone lamps lit up the low room with a hazy light; across the side opposite to the entrance a space 6 by 8 feet was curtained off with deer-skins, and in front of it was a model of a tree suspended from the ceiling, and, as the knowledge of the native who designed it was comined to the few pieces of drift-wood found on the beach and some pieces of timber cast ashore from wrecks, the specimen was unique; it consisted of two oblong boxes open at both ends loosely attached together endwise with seal thong; the part representing the body was 2 feet long, 8 inches square, and that representing the top 18 inches long and 6 inches square, and was suspended by a thong with the lower end two feet from the floor. On the right and left of the tree hung the skull of a wolf and the dried carcass of a raven; two of the singers sat flat upon the floor with their legs extended, one close behind the other, the foremost one with his nose just touching the tree. As soon as all were in position the drummers, accompanied by the women, struck up a doleful chant to which the man at the tree kept time in his supplications to (Tuña) the Great Spirit to give them success in pursuit of whales, deer, seal, &c., and to send white men with plenty of rum and tobacco; and he particularly dwell upon certain articles he knew we had at the station; at the same time he beat the body of the tree with a wand. As he completed his schedule of wants the lower edge of the curtain was raised and five natives crawled forth on their hands and knees. They were dressed in the skins of the bear, wolf, lynx, fox, and the dog,t he heads being dressed complete, showing the grinning teeth. On their hands were large mittens of dried seal-skin, with shells and small pieces of copper attached with pieces of thong, so that they swung and rattled as they moved their heads. They crawled slowly forward, swinging their heads in unison, keeping time to the music in hoarse growls, and by shaking their huge mittens until their heads touched the singers by the tree, when they all sprang to their feet with a loud shout, and the performance was brought to a close by all joining in a wild shout accompanied by spasmodic gestures that seemed to threaten a dislocation of their joints.

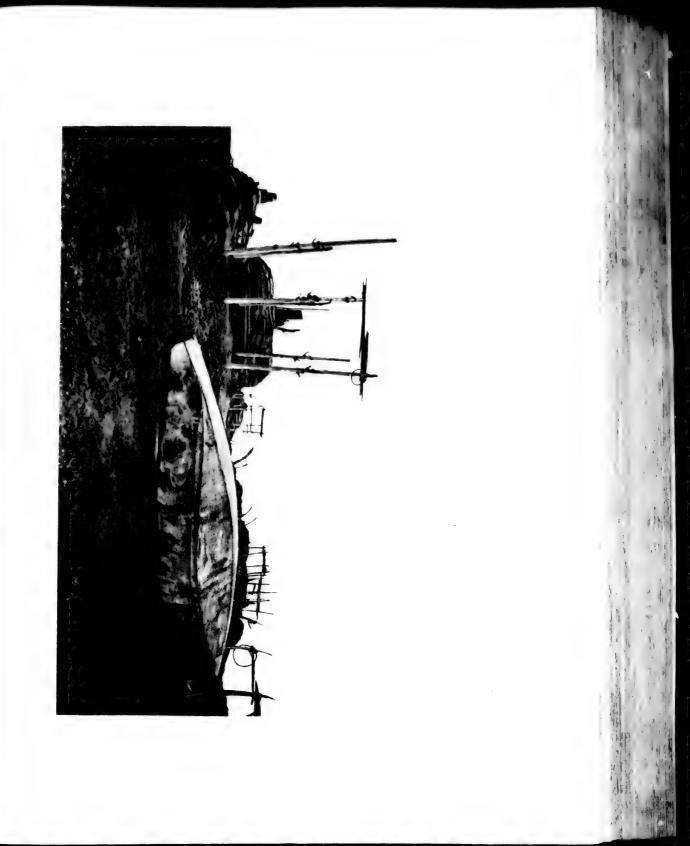

As we came out in the open air we found another party just commencing the out-door dance, and so they kept it up night and day. Each party as they completed their dance were feasted by friends in different iglus. The invisible spirit (Tuña) peoples the earth, sea, and air; we never could find that they gave it any place of fixed abode; visible at times, as many of the old men insisted that they had seen him, and described him as resembling the upper part of a man, but very wide, with an extremely large head and long fangs; he is the creator of all things, and also the destroyer, is ever to be feared, especially in the night, and men and women, when out at such a time, usually carry a large knife to defend themselves should they meet him. That they believe in ghosts was apparent in the case of a woman who had been doing some work for our party. Coming to the station one day and being asked to mend a pair of gloves, said she dare not, as there was a dead man in the village, and his body had not yet been carried out; that he would see her and some evil would befall her. Upon being urged, she first obtained her husband's permission, and then seating herself in the middle of the floor, she drew a circle around her with a hone snow-knife she carried, and remarked that now he could not see her; she was very careful to keep her work all inside

the circle, and would not leave it until all was completed.

They dislike to go out on a dark night, but if obliged to, they generally carry a bone or ivory snow-knife or a long bladed steel knife, to keep off Tuña and Kíolya (Aurora), which they believe to be coually evil; but Tuña especially is concerned in producing all the evils of life. Should the whales fail to put in an early appearance, the birds fly high or far out over the pack, the shore lead open late, a gale blow down their caches and break their gear and boats, the old and wise would meet in solemn conclave to devise some means whereby the works of Tuña shall be exorcised and he shall be driven forth from the village. Various means are resorted to; the most common one is for the principal men to meet and (abawa) talk, chanting together in a loud tone, accompanied by beating of drums; they call for the east wind (nigyû) to blow on the ice (siko) to open it. Individual wants are by personal supplication, and to them, earth and air are full of spirits. The one drags men into the earth by the feet, from which they never emerge; the other strikes men dead, leaving no mark, and the air is full of voices; often while traveling they would stop and ask me to listen, and say that Tuña of the wind was passing by. With the return of the sun he is hunted out of each iglu by incantations that would daunt the boldest spirit. A fire is built in front of the council-house, and at the entrance to each iglu is posted an old woman wise in ghost lore; the men gather around the council-house while the young women and girls drive the spirits out of the ight with their knives, thrusting them under the bunk and deer skins in a vicious manner, calling upon Tuña to leave the iglu; after they think he has been driven out of every nook and corner,

they showith ing. time agai spiri char one to ha we a every iglu. tranc roof; drag ened that relat man, and derectiney usual ing tibroughow ground on a soon
The area of the she to retur coast have somet slight not at of du seque other weigh T mittee with t they drive him down through the hole in the floor and chase him out into the open air with load shouts and frantic gestures. While this was going on the old woman at the entrance, who was armed with a long knife used for cutting show, made passes over the air with it to keep him from returning. Each party drove the spirit towards the fire and invoked him to go into it; all were by this time drawn up in a half circle around the fire, when several of the leading men made specific charged against the spirit; and each, after his speech, brushed his clothing violently, calling upon the spirit to leave him and go into the fire; two men now stepped forward with rifles loaded with blank charges while a third came with a vessel of urine, which was thrown upon the fire; at the same time one fired a shot into it; and, as the cloud of steam rose, it received the shot, which was supposed to have finished him for the time being. While they were ever threatening or supplicating Tuña we never knew them to offer thanks or be grateful for any benefits he was supposed to bestow; everything they received was taken as a matter of course, and as the result of some particular incantation.

I saw a very ingenious contrivance an old man had rigged up to keep Tuña from entering his ight. He had his seal drag, which was fitted with a carved ivory handle, suspended over the entrance inside his hut; the thong was fastened by his hunting knife being driven through it into the roof; he explained to me that Tuña in coming in would catch hold of the handle of the seal drag to help himself through the hole and would pull the knife down upon his head and be frightened away. He contemplated his contrivance with a great deal of satisfaction, and assured no that Tuña was very much afraid of his ight.

Their dead are carried out and laid on the tundra without any ceremony other than the near relatives following the body to its last resting place; it is usually wrapped in deer skins, and if a man, his sled and hunting gear are broken and laid over the body; if a woman, her sawing kit and some few household utensils are placed at her head, but everything so left is broken and rendered useless. With but few exceptions I never knew them to pay any attention to their dead after they were carried out, and all showed great reluctance about speaking of them. The bodies are usually eaten by the dogs, especially in the winter, and it is no uncommon sight to see them grawing the bones on the roofs of the iglus. The sled used to carry the body out on the tundra is not brought back to the village at once, but left out on the tundra not less than two moons, and while they all claim that it is bad to use anything that belonged to the dead, I noticed that no matter how good an outfit he had while living his was the most worthless sled and gun that could be found, and I knew of a number of cases where there was a general division of a dead man's effects on a basis of first come first served. As a rule the dead (Nu'nami-sintk, on the ground asleep) are soon forgotten, and the names of the noted whalemen or hunters only live in legend.

There is no marriage ceremony among them, but children are often betrothed by their parents ar an early age, and this promise is very faithfully kept, and they enter upon their marriage relations at the age of twelve to fifteen years; where there has been no childhood engagement the mother makes a selection of the wife for her son, and the girl selected is invited to the house, where she takes the place of a servant for a short time, doing the housework and cooking, generally returning to her father's iglu to sleep. They usually avail themselves of the summer trip along the coast or into the interior, and take upon themselves the full obligations of marriage. They often have family disagreements, the husband resorting to blows when the wife is sulky and disobedient, sometimes with the result of her running away; and we knew of one instance where, owing to a slight mistake the husband had made in his estimate of his wife's character, he obtained results not anticipated, for while out on a deer hunt he attempted to chastise her for some fancied neglect of duty when she retaliated, and, being the stronger of the two, she gave him a severe thrashing, and then taking with her an adopted child she fled to a village seventy-five miles away. She subsequently gave up the child, but would not return to him, and soon after became the wife of another man. At the time we landed at Uglaamie this same woman carried on her back a box of lead weighing two hundred and eighty pounds a distance of over two hundred yards.

The women as a rule seem to have an equal voice in the direction of affairs, when once admitted to the position of wife, and in each village there are a number of old women who are treated with the greatest consideration by all, they being credited with wonderful powers of divination, and are consulted in all important affairs. And the wives are treated with more consideration by

their husbands than they are by savages of the lower latitudes, though to her falls the dradgery of housekeeping, dressing skins, and making boots and clothing; his task is equally hard, as he is exposed to the dangers of the ice and storms in the pursuit of seal and deer, often returning to his iglu completely exhausted. She aids and assists him by following his trail with the dogs and sleds to bring in the game which the hunter catches in the snow where he kills it, setting up a cake of snow or ice with his mark upon it, to mark the place. The wife is invariably consulted when any trade is to be made, and the husband never thinks of closing a bargain of any importance without her consent. When traveling they take turn about in leading out ahead of the team, and all assist in building the snow but when camp is made. The wife also has the care of the dogs, with whom she often shares her food, giving as much care to the puppies as she would to a child, carrying them in the back of her altega or wrapped in skin on the sled when traveling, until they are old enough to be harnessed into the team, when by their faithfulness and endurance they make full return for all kindness shown them in their childhood (puppyhood), and although a dog team would try the patience of a saint, they never use a whip and rarely strike them; they coax and encourage them along by the voice; and often toward the end of a journey they hasten their pace by dragging a piece of resh meat by a string in front of the team, being careful to keep it just beyond their reach. They give the most careful attention to their foot-gear, especially when traveling during the winter; and here a woman's services are invaluable, as she is very expert in the use of her needle, and she dries and repairs the boots of the party before she sleeps; this is necessary owing to the frail character of the skins used in making their winter boots. Men do such work when alone, but not so well as the women. She also carries a sealskin water-bottle on her back under her "alige," which is replenished with snow after each draught, and is their sole dependence for water on long, rapid journeys during the winter.

Large families are very rare, and children are born at intervals of from two to four years; they do not often bear children before twenty, and a couple is very seldom met with that has a family of more than three, though upon inquiry they may have some that "nuna-mi-sinik," sleep on the ground," and where the people are poor it is not unusual for a mother to give away all but the first-born to some couple that have no children; boys are in greater demand than girls for adoption, and the adopted mother gives it all the care she would a child of her own, and will rarely if ever tell who the real mother is. So it is very difficult to trace the antecedents of any one man, for during his childhood he may have passed into two or three different families by adoption, and many of them do not know who their mother is, much less their father, and matters are still further complicated by a custom of exchanging wives. This is often done when a man is obliged to make a long trip, and his wife from any cause is unable to accompany him. He will exchange with some friend who has an able-bodied wife, each entering upon their new relations with the

greatest cheerfulness.

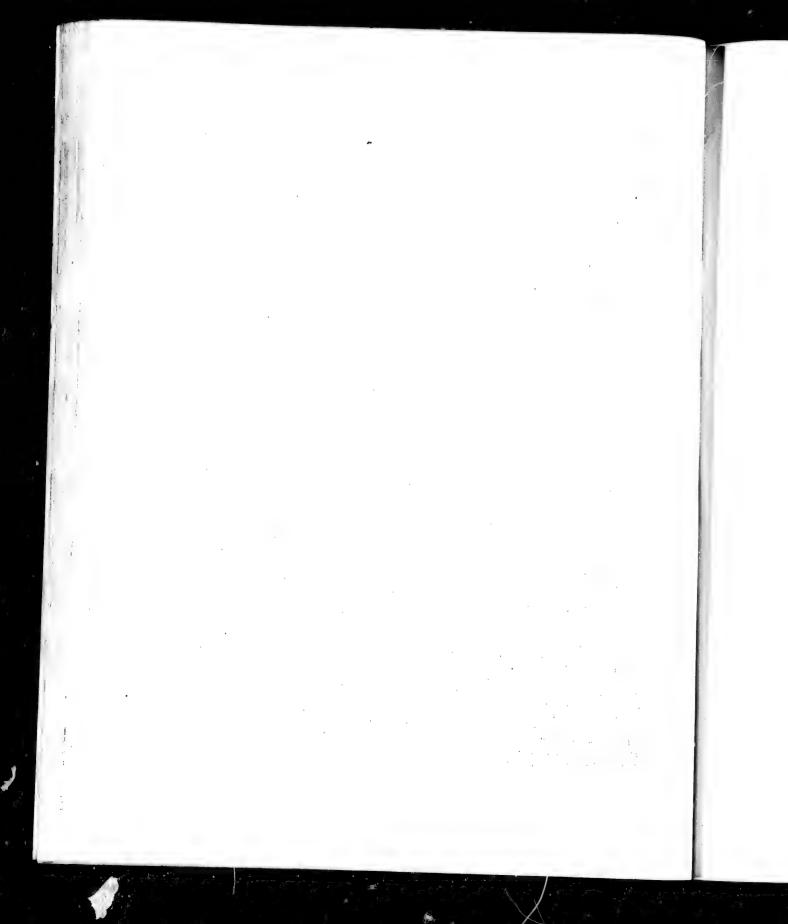

Polygamy is not common, being confined to the leading influential men; even then, they are taken into the family more as assistants for the first wife, as she rules over them, treating them as servants; the system is not popular among the women, and we knew instances where the first

wife abandoned the iglu in a rage when a second was brought home.

When a man of matured years loses his wife, either by death or from incompatibility of temper, he selects one for himself, and that they sometimes use force to coerce them, when they have no near relations to protect them, I am well satisfied from an incident that occurred at the station. A native from a village to the westward, whose wife had left him, came up to Uglaamie to obtain another; one day we were attracted by loud outcrics from a woman who had been waiting around the station for food, and upon going out to see what the difficulty was, we found our friend from Sidarn vigorously enfling her ears, and it was some time before we could make him desist; as soon as she got free from him she ran off, and he explained that he wanted her for a wife, but that she was not willing to go with him, and he was persuading her. His courtship was certainly unique, and I never heard that he succeeded in winning the affections of an Uglaamie maiden, and it is but just to add that he was very unpopular among both men and women.

The tie of relationship binds them to deeds of kindness that they would not show to people outside of the family; if a brother dies the survivor takes the family to his iglu until he can find another husband for the widow, and we know of an instance where a man lost his wife, and his

PRAITINA TERRITOR OF NUMBER

port port her vide after on c as h had it; b

be for tend main freel, son 1 after up a more but t nets day's it was rule left. Coming the time of the coming the coming the time of the coming th

brother who had two (who were sisters) gave him one. Their efforts to get husbands for the widows of dead relatives were often very amusing. Mû/ñialu, a hunter employed at the station, was supporting his widowed mother, who was a great scold; he brought to his iglu several candidates for her hand, who had been induced to take the step by Mû'ñialu offering to make them presents provided they would take her, but a few days or weeks was about all the most patient could bear; after several trials and failures among the men of Nuwak and Uglaamie, he finally gave it up, but on one of his trips to the eastward he brought back with him a Nunatáñ-meuñ from Colville; as he was quite deaf and could not understand the Uglaamie language very well, her shrewishness had no effect upon him, and Mûñi was happy; he would laugh immoderately when talking about it; but never, through it all, was he disloyal to his mother; she always had a place in his ight, plenty to eat, and was always treated with the greatest respect.

In the treatment of their aged and infirm parents, the example set by these people could well be followed by many of the more civilized nations to their advantage; they never forget the tender care they received in their childhood, and as their parents growedd and are unable to maintain themselves the children display the greatest devotion. The first fruits of the chase is freely given up to them, and no project undertaken without their approval; and in all things the son remains obedient to the father so long as he lives, and speaks of him with the greatest respect after his death. In their summer journeyings, should they wish to remain at home they fit them up a tent (tupěk) in some pleasant locality, and leave them an abundant supply of provisions, but more often accompany them in their wanderings, being comfortably transported by sled or boat; but the old people are rarely idle, for while the father busies himself making new seal spears and nets the mother assists in providing clothing and boots and dressing skins. We often had our day's journey brought to a sudden termination by some old woman in the party announcing that it was time to go into camp because she wast tired or cold, and nothing we could say would overrule her decision.

Owing to the exposure and hardships they are obliged to undergo in the struggle for existence they very rarely attain a very great age, and the majority by far die under the age of forty years, and a man at sixty becomes very decrepit. They have no means of keeping a record of their age, and it is generally calculated from some event connected with their history, as the coming of some ship, or a time of famine or pestilence. There was one man at Uglaamie, on board H. M. S. Plover, Captain Maguire, in 1853 and 1854, who, Captain Hull (who was master under Maguire) informs me, was about thirty years of age when the Plover passed her winters there; at the time of our visit he was very decrepit, was bent nearly double, and crawled rather than walked, with a staff in each hand; his shriveled skin, toothless gums, and shrunken limbs gave him the appearance of great age, but he could have seen but little more than sixty years, if that. I met several who said they were children in Magnine's time, and they had every appearance of men of

forty-five or fifty.

That the race is rapidly decreasing is shown by the fact that during the two years we were on the coast, in the village of Uglaamie alone, there were eighteen deaths and only two births in a population of one hundred and thirty souls; and Dr. Simpson states that in 1854 the village had a population of over two hundred. He also reports forty iglus, while we found only twenty-six. At Nuwuk, he reports forty-eight iglus, and two hundred and eighty-six people. We found this village had dwindled to thirty iglus, and less than one hundred and fifty people; and the freshlycached bodies and numerous half-ruined iglus bore silent testimony to the fact that famine and disease had quite recently been at work. This is undoubtedly owing to the fact that the foodsupply is rapidly growing less, and that the great number of whales taken off the coast by the American whaling fleet during the last twenty years has nearly exterminated that valuable animal. That they are decreasing in numbers is well known among the whalemen, and the fact that Dr. Simpson reports that during the time the Ployer was at Point Barrow there were twenty-four whales taken by the natives, while only two were taken during our stay, one of which was a calf, goes to prove that they will soon be classed among the extinct mammals, and with them will soon pass away many of the people inhabiting this shore; they are slow to take up with an innovation, and they do not really adapt themselves to the new condition of affairs which the loss of this great foodsupply has brought about. The seal are not numerous, and often leave this coast entirely for a season. When this occurs, famine with all its horrors is upon them, and they have no place to flee to for help. During the first winter at the station, food became very scarce, and scarcely a day passed but some poor native, with starvation written in every line of his face, hung around our doors begging for a mouthful of food. We gave them all we could spare with safety to ourselves, and undoubtedly saved many lives. Walrus hide and pieces of old boat-covers were considered delicacies, but we never knew them to resort to violence to obtain food, and cannibalism is looked upon by them with horror, and I could not find that a case had ever occurred. They will not even eat their dogs. Some seasons a few white whales (Beluga) are taken. The skins of this animal are in great demand for soles to water-proof boots, and often bring a high price.

Dr. Simpson reports that quite a number of narwhal were taken on the coast during the stay of the Plover, but I could find but one Indian that had ever seen one, and they are not common in this ocean at the present time.

Physically, both sexes are very strong, and they possess great powers of endurance; are capable of making long journeys on foot, with a very small allowance of food; in fact, when food is at all scarce, or while traveling, they never cut but once each day, and it was a surprise to us to see them when on a journey get out before daybreak, and, without taking a mouthful of food, make a journey of thirty or forty miles before breaking their fast; and they treated their dogs in the same manner, saying that they traveled better when fed only at the end of the day's journey; sometimes they would give them a mouthful apiece toward the middle of the day, but the practice was looked upon as bad.

The flint and steel is the most common method of procuring fire, using for tinder the down from the seeds of plants, impregnated with mealed powder or charcoal. Sometimes two pieces of iron pyrites are used, and we found the ancient fire drill still in use among some of the old, conservative men; the drill was a shaft of spruce eighteen inches long and three-fourths inch in diameter, the lower end terminating in the frustum of a cone, the upper end made to fit the socket of a stone rest that is held between the teeth; a block of hard wood with a small cavity in the center is used as a friction block; a small quantity of tinder is placed in the bottom of the cavity and the drill pressed down by the mouth-rest and turned rapidly with a small bow like a jewcler's bow. They are anxious to obtain matches, but they are not considered a necessity, and will not buy them as a rule. Flints are an article of traffic, and are brought from Cape Lisburne and the Romanzoff Mountains, there being none indigenous to this part of the coast. They believe that the pyrites come down from heaven in the form of meteors, and they call it fire-stone for that reason.

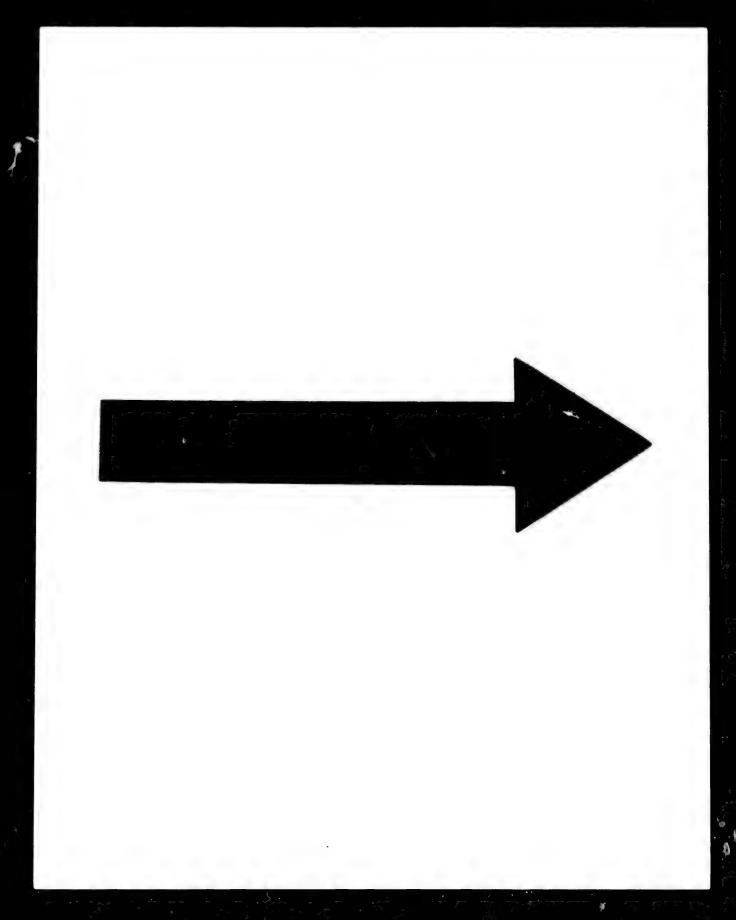

The children receive the tenderest care, and we never saw one punished by its parents. It is no unusual sight to see a child nourished at the breast until it is four or five years of age; this is especially the case with boys, who, as a rule, receive more care than girls. His food is carefully selected by his mother, and he is enjoined from eating certain articles that have been tabooed by some old woman, usually a relative; and this prohibition extends through life. With each individual there is always one or more article of food from which they carefully abstain, though the pangs of hunger may be upon them, and, as an old man expressed it, when declining a piece of bear meat, "It may be good for all men but me," shows the individuality of the custom.

To us the treatment the women receive during confinement seems harsh in the extreme, and it is a matter of surprise that either mother or child ever survives the ordeal. Several days before her confinement the mother is placed in a small snow hut, if in the winter, and in a small tent, if in the summer; no one is allowed to go near her, except her husband, who brings her food and passes it in to her without entering the hut. Here she remains entirely alone until the child is one moon old. Should the child die, then she can return to her husband and iglu after eight or ten days. No person will knowingly drink from the same cup or eat from the same dish that a woman has used during her confinement until it has been purified by certain incantations. And any woman who has suffered from premature childbirth, or given birth to a child during the winter, is allowed to go into a canoe or out into the pack during the spring. Premature childbirth is of frequent occurrence among them, and we frequently noticed the greatest solicitude on the part of the husband to guard the wife from any accident during pregnancy.

During the long winter night, when food is plenty, they delight to meet at the council-house. or at different iglus, and over their work recount, recall, different events of their lives, and repeat the legends of their race, which have been handed down from father to son, to which the young people listen with rapt attention. These legends go back to the origin of man, and they tell with care full detail of a time when there were no men in all the land, but that a spirit called "a-se-la" dwelt here alone, and that he made the image of a man in clay, set it up by the shore of the sea to dry, and after it was dry he breathed upon it and gave it life and sent it out into the world. And he called the dog from a long way off to go with man, that he might have help in traveling. After a time the spirit made the Tuk-tu (reindeer) and sent him out into the land, and the teeth of the deer were like the teeth of the dog. After many days man came to the spirit and said. "The deer is bad, he devours man." Whereupon the spirit called in all the deer and removed all the front teeth from their upper jaws, since which time men have lived on deer, and the deer have lived on moss and grass. Then the man asked the spirit that there might be fish in the rivers and sea. And the spirit took a piece of pine and a piece of balsam and sat by the river where it emptied into the sea, and he whittled long shavings from the pieces of wood, and the shavings fell into the water, and the shavings from the yellow wood became salmon, and those from the white wood became whitefish and swam away.

Their faith in these legends is very strong, and they are extremely opposed to any expressions of doubt or ridicule, and it is only by gaining their confidence and abstaining from any expressions of doubt in their presence that they can be induced to talk about their people or repeat their legends. We heard but one legend that referred in any way to the regions to the northward. It was said that many generations ago a man from Nuwük was caught in the moving pack that was setting to the northward so rapidly that he was unable to return to the land. After a great many days, more than he could count, he came to a land where dwelt a strange people; they spoke a strange language, and dressed in deer skins like the inyu. He remained with them a long time, but, wishing to return to his people, he left them one winter and started south over the ice, living upon the seal he caught by the way, and renewing his boots with their skins. The journey was so long that he wore out fifteen pairs of boots in returning to Nuwük. Dr. Simpson reports a similar legend told him during his stay.

They all have a natural craving for rum and tobacco; it is always the first thing they ask for when they come to trade, and they are never satisfied unless they can get sufficient rum to make them dead drunk. The old men deprecate its use, and will tell how bad it is, and how certain men were killed in drunken fights, and will be very strong in their denunciations of its use so long as they cannot get it, but generally fail to resist the temptation when it is offered to them, or an opportunity occurs for them to get it. Fortunately there is but little to tempt the trader to this region, and the little they get from the whale ships is consumed on the spot, so there is no drunkenness after the sea is closed. Their tobacco they hoard carefully, and it is used by old and young in quantities only limited by the supply; they prefer a black-leaf Russian tobacco, but this is hard to get, as only small quantities of it reach this coast by the way of Behring Straits and the Diomede Islands. Next to this they prefer the black navy-plug of the commonest kind. Men and women both smoke and chew, and the children are given tobacco in their earliest infancy. It is no uncommon sight to see a child not old enough to walk lying asleep with its cheek distended with a huge chew, or to see a woman with an old quid behind each ear which has been thoroughly masticated, and put up to dry, for the future use of her lord and master. Chewing does not seem to have the slightest deleterious effect upon the children, while smoking affects the men very seriously. Their pipes are made of either stone, wood, or ivory, and consist of a flanged bowl, from one and one-half to two inches in length, with a bore one-fourth of an inch in diameter, attached to a curved wooden stem made from two pieces of wood grooved and lashed together with seal thong; the bottom of the bowl they fill with deer hair and place on top of it a piece of tobacco about the size of a pea. It is all consumed at one whift, and they hold the smoke in their bangs until they become nearly sufficiated; a violent fit of coughing follows each smoke, and with the old men it frequently so prostrates them that they are quite unable to walk for some little time after each indulgence. From what the old men told us, and from some ancient stone pipes found in the ruins of aucient iglus, it would seem that they smoked before tobacco was known among them, and they

used a kilikinic) made from the eatkins and bark of the arctic willow, which they now use to adulterate their tobacco. They all seem to have a natural appetite for this weed in any form. The men would often beg the privilege of cleaning the deposit from the stem and bowls of our pipes, which they are with great relish, and, strange to say, without being nauseated in the slightest.

That these people have not yet made the transition from the stone to the iron age is shown by the large number of stone and bone implements still in use among them at the present time. Many of the old conservative men still cling to the habits of their fathers, and believe that stone arrow and lance heads possess virtues that makes them superior to those made of iron. They still teach the young men the art of chipping flint, and over their work tell them of the happy days before the white men came to drive away the whales and walrus, and when food was always plenty. An old man, when asked what he would do without the things the white men brought them, answered it would be very hard, and then to show us what he could do he showed a pair of boots he had on, and told us with great pride how, when his boots gave out while hunting, he killed a deer, made a needle from a piece of his bone, thread from the sinew, and made himself a new pair of boots from the skin, and asked, Could a white man do that? In the spring of 1883, when they came to prepare their boats for whaling, they decided after many grave debates that the bad luck of the previous year was owing entirely to their having equipped their boats with white man's gear, of which they had abundance, obtained from wrecked whalers; so it was decided that they would go back to the implements of their fathers, and the old ivory and stone harpoon and lance heads were brought forth and repaired, and that they took one whale was attributed entirely to this change; the fact that the whale was killed by a shot from a bomb gun we loaned them to the contrary notwithstanding.

From the head of Kotzebue to the mouth of the Mackenzie there is not found any timber of any size indigenous to that region, and the Colville, Ik-pik-pûñ, and Meade River bring down no drift of any size, only the arctic willow. The drift cast up by the sea consists chiefly of spruce, birch, and poplar; it often comes ashore with the bark and roots intact and but slightly water worn. That this drift comes principally from the Mackenzie is shown by the fact that it is found in great abundance to the eastward of Point Barrow, while to the west of it not so abundant. We occasionally saw large trunks of trees, from two to three feet in diameter, stripped of roots and branches, generally of cottonwood, which seemed to have been a very long time at sea. What little drift we saw coming from the westward was always old.

The streams that have their source in Meade River Mountains bring down no drift larger than the arctic willow, and we saw no drift along the arctic shore that resembled that from the Yukon, found along the shore of Norton Sound. The natives in the vicinity of Point Barrow are always on the lookout for pieces of drift wood, and every piece that can be utilized in building hut or boat is at once marked and placed above high water. At leisure they work them down to the size required, stick them up so as to show above the snow in winter, when they are hauled to the iglu and placed on the cache. It is often a work of from three to five years to accumulate enough timber to construct a boat or iglu. Every cache shows a store of neatly dressed sticks, that are highly prized, and that have a commercial value.

In the small inlets along the coast drift wood was found from ten to fifteen feet above the highwater mark of the sea, and at first we were led to believe that such drift represented an unusually high tide, but we subsequently learned that it was caused by the heavy ice pack, which, in the winter, is forced in on the land by the violent gales, and makes a dam across the entrance to the inlets. The water from the melting snows in the spring fill up the inlets and finds no outlet until it overflows this barrier, when, running down rapidly, it leaves the drift high above the sea level.

These openings, seen in the early summer, have often been mistaken for the mouths of rivers by people passing on ships. It is very doubtful if this vast stretch of country contains anything that will ever render it of any commercial value to the world. But on our voyage south we were struck with the fertile appearance of the Aleutian Islands where we halted for a few days to repair our vessel. On the island we visited, though late in September, we found a luxuriant growth of grass still untouched by frost. All the islands we saw were high and rolling, intersected by beau-

gh-illy the the ntil vel. by hat ere pair a of au-

tiful valleys, watered by streams that abound in excellent trout. They were destitute of timber, but we could see no reason why they should not be valuable as grazing lands. The climate is similar to that of Ireland, and in about the same latitude; the lowest recorded temperature in seven years is -6° F., and the annual mean is.

The great Japan current gives to these islands a climate peculiarly mild and equitable for so high a latitude, and I think a careful geological and geographical survey would develop valuable resources.

# NATURAL HISTORY.

By John Murdoch, A. M., Sergeant Signal Corps, United States Army.

#### INTRODUCTORY.

The following report on the Natural History of the Point-Barrow Expedition is presented by the writer, to whose charge the collections and notes were intrusted. Part of the material has been turned over to specialists for study, and part has been worked up by the writer himself.

The writer desires to express his thanks to Prof. S. F. Baird, director of the United States National Museum, for affording him every possible convenience in the way of laboratory accommodation at the Smithsonian Institution, and access to the libraries of the Institution, as well as for much valuable assistance and advice. He is indebted to the curators and assistants of the Museum, especially to Messes, Robert Ridgway, Richard Rathbun, W. H. Dall, and T. H. Bean, for much willing and valuable assistance and advice. To Mr. Dall he is also particularly indebted for access to his valuable library.

He desires especially to acknowledge the assistance rendered him by Mr. James E. Benedict, naturalist of the U. S. Fish Commission steamer Albatross, who placed his books and his time at the writer's disposal, for the identification of the collection of Worms,

Prof. Asa Gray, of Cambridge, Prof. C. V. Riley, of the Department of Agriculture, Mr. W. H. Dall, of Washington, and Mr. J. W. Fewkes, of Cambridge (the last as a personal favor to the writer), have kindly prepared special reports on the Plants, Insects, Mollusks and Acalephs, respectively.

Professors A. E. Verrill and O. Harger, of Yale College, and A. S. Packard, jr., of Brown University, and the Bon. Theodore Lyman, of Massachusetts, have kindly furnished the writer with valuable assistance and many suggestions.

The Eskimo name of each animal has been appended wherever it was possible to obtain it. The report consists of the following divisions:

- L - Mammals
- II. Birds.
- III.- Fishes.
- IV. ... Insects.
- V. -Marine Invertebrates, exclusive of Mollusks
- VI. Mollusks.
- VII. Collecting-localities and dredging-stations.
- VIII. Plants

#### APPENDIX

- A.- Notes on Surface Life under the Seasice.
- E.—Notes on Surface Life, observed during the voyage from San Francisco to Point Barrow, and during the season of open water at Point Barrow.
- C. List of Bird's noticed at Ployer Bay, Eastern Siberia

### I.-MAMMALS.

By John Murdoch, A. M., Sergeant Signal Corps, United States Army.

The following report contains all the information we were able to gather concerning the mammals inhabiting that portion of Northwestern Alaska traveled over by the Eskimos of Point Barrow in their hunting and trading expeditions.

From the character of the country and the necessarily confining nature of our duties at the station, much of it was obtained by hearsay from the natives, though the exploring and hunting expeditions made by Lieutenant Ray and Captain Herendeen added considerably to our knowledge

Marine mammals, of course, predominated in the immediate vicinity of the station, the Arctic Fox and the two species of Lemming being the only land mammals that were at all abundant. Of the larger mammals the most abundant are the Reindeer and the Ringed Seal, which form the staple food of the natives.

### LIST OF MAMMALS.

- 1 Canis occidentalis grisco-albus Bd. Wolf (Amázo).
- Vulpes fulvus (Desm.) DeKay. | Rud Fox (Kaià/ktūk, Kanā ktua).
- Vulpes fulvus argentatus Aud. A. Bach. BLACK Fox (Kaià ktûk).
- Vulpes lagopus (Linn. : And. & Bach. Arctic Fox (Teri gânia).
- Gulo luscus (Linn.) J. Sab. WOLVERINE (Ka bwin).
- Putorius erminea (Linn.) Griff. | ERMINE (Teria).
- Ursus arctos? Barren-Grot No Bear (A kqlak).
- Ursus maritimus Linn. Potar Bran (Nd nu).
- Phoca vitulina Lian. HARBOR SEAL (Kasigi'a).
- Phoca feetida Fabricius, Ringlib Seal (Ne'tyi).
- Erignathus barbatus Fabricius Gill. BEARDED SEAL (Ug'ru).
- Histriophoca fasciata (Zimm. Gill. RIBBON SEAL (Kaixóliñ). 11.
- Odobænus obesus (III. Allen Paciffic Walkus (A ibicik), 12
- Ovibos moschatus (Gnall) Blancy. MUSK OX (Umam.tu).
- Ovis montana 7 · Cuv. Mountain Sheer; Bighorn (I minea). 14.
- Rangifer tarandus grænlandious (Kerr.) REINDEER (Ticktu), 15
- 16. Elephas? sp. MAMMOIN Kelegway.
- Beluga sp. White Whater Kelelyne
- Orea sp. Killithia 1 18.
- Monodon monoccios Lina. Narwhall (Tunt ) -19.
- 20. Balana mysticetus Linn. Poran Whale: Bownead (Akbuák).
- Sorez forsteni Rich. Tousinu's Smanw Mouse (Ug'ru nû),
- 22. Myodes obensis Brants. TAWNY LEMMING (A rwifeld).
- 23. Cuniculus (erquatus Pall.) Cones, HUDSON'S BAY LEMMING.
- Spermophilus empetra (Pall.) Allen. PARRY'S SPERMOPHILE (Schsin).
- 25. Lepus timidus arcticus Allen. POLAR HARE.

#### 1. CANIS OCCIDENTALIS GRISEO ALBUS Bd.

Wolf (Amáxo).

The Wolf never appears to come near the coast in the vicinity of Point Barrow. The natives, however, have a good many of their skins and prize them very highly for trimming their deer skin clothes, especially for making the frill round the hood of the jacket.

The skulls also are highly valued as amulets or fetishes, and no whaling umuk is regarded as properly fitted out unless provided with one or more wolf-skulls.

The natives speak of them as rather plenty inland along the rivers where the reindeer abound, and say they chase the deer in packs.

Our hunting and exploring parties which went inland in the spring of 1882 and 1883 saw wolves several times but were unable to secure any specimens. The only skin we obtained, a very large male, was shot by a native hunter near Meade River in the spring of 1883.

One of the Eskimo trading parties which went east in the summer of 1882 succeeded in catching a couple of male cubs alive. These were brought home early in September, and carefully fed till late in December, at which time their fur was supposed to be fit for use. They were then killed with much ceremony, with a stone-headed arrow.

The natives appear to regard the Wolf with a certain amount of superstitious reverence. A man who has killed a Wolf must sleep out of doors in a tent or snow ight, for one "moon" from that time.

We obtained one skin and six skulls.

### 2. VULPES FULVUS (Desm.) DeKay.

RED FOX (Kaiāktūk, Kanā'ktua).

#### 2b. VULPES FULVUS ARGENTATUS Aud. & Bach.

Black or Silver Fox (Kaia'ktuk).

A few skins of Black and Red Foxes came in among the furs obtained by the trader at the station. They were all, however, said to have been obtained by trade from the tribes further to the east.

One of our native deer-hunters last spring (1883), however, came in with a report that he had seen and wounded a Black Fox near the hill Nuasū'knan, which is close to the upper Meade River. No skins of the cross fox (V. fulvus decussatus) were found among the trade fox-skins.

### 3. VULPES LAGOPUS (Linn.) And. & Bach.

ARCTIC FOX (Teritgânia.)

The White fox is quite abundant near the station, especially in winter, when their tracks are to be seen in the snow all over the tundra. They are, however, so exceedingly shy, and so well protected by their white covering that the animals themselves are seldom seen at this season.

During the egg season, that is, through June, they may be frequently seen "quartering" the tundra in search o' eggs and sitting birds, particularly at night, and are occasionally found running along the beach. Their speed when alarmed is very great. They seem almost to fly over the ground instead of running.

Though usually very wild, hunger sometimes renders them quite bold and familiar. In the spring of 1882, one of the women at the hunting camp on Meade River found one in the meat house and easily killed him with a stick.

They are, in general, pretty widely scattered over the country, but sometimes gather in large numbers where there is any particular supply of food.

The Eskimos reported in February 1882, that there were great numbers of them one day's journey to the east feeding on the carcass of a whale that had been washed ashore. Any game

that is left out over night must be carefully covered up with slabs of snow or it will be soon caten by the foxes.

A good many of them are caught by the Eskimos, either with steel traps or "figure-of-four" traps of their own construction. In using a steel trap they do not bait the trap itself, but place the bait in a little house made of slabs of snow. The trap is set and carefully buried in the snow at the doorway of the house so that the fox must step on it in his endeavors to reach the bait.

They build a similar house for their "deadfall" or "figure-of-four" trap, and arrange the log above the door of the house so the fox brings it down across his back when he reaches in for the meat.

The trader obtained a large number of White Fox skins, mostly in fine condition with very acayy thick fur. Out of the number there were two or three in the "blue" condition, also heavy winter skins.

The summer pelage seems to be completely assumed by the middle of July. A female shot close to the station, July 8, 1882, had the brown summer coat very short and thin, with bunches of white fur still adhering to it, and a few scattered white hairs still remaining. She was very thin and dirty, and about as miserable a looking creature as could well be imagined.

In 1883, a female in nearly the same pelage was taken at Woody Inlet with her two blind cubs, about the size of new born kittens. They were the color of a Maltese cat.

They were very rarely seen after the middle of July until well into October, when they became quite plenty and by that time had again become completely white.

Their tracks were occasionally seen out on the sea-ice, where they had wandered, perhaps in the hopes of pickings of seal offal, after some bear, or perhaps in pursuit of stray lemmings or ptarmigans, that every now and then get out upon the ice.

### 4. GULO LUSCUS (Linn.) J. Sab.

### WOLVERINE (Kathwin).

The Wolverine was never seen by any of our parties nor reported by the natives. Wolverine-skins, however, are very plenty among the Eskimos, and highly valued for trimmings. The tail is especially sought for as an ornament to be worn at the back of the belt.

All these skins are brought from the interior, and are generally obtained by trading.

### 5. PUTORIUS ERMINEA (Linn.) Griff.

### ERMINE (Téria).

Skins of Ermines, both in summer and winter pelage, are common among the natives, and are occasionally worn as trimmings or anulets. During the winter their tracks and droppings were occasionally to be seen on the tundra. An adult male in full summer pelage was shot close to the station early on the morning of July 16, 1883.

### 6. URSUS ARCTOS ?

### BARREN-GROUND BEAR ? (Å/kglak).

There is a brown bear in the interior, of which we were unable to secure a specimen, and which is probably Richardson's "Barren-Ground Bear". The natives had several more or less mutilated skins, which in color closely resembled the cinnamon bear

The Eskimos say that the "land bear" is abundant during the summer in the neighborhood of Meade River.

### 7. URSUS MARITIMUS Linn

#### POLAR BEAR (Nä'nu).

Polar Bears are by no means so abundant about Point Barrow as might be expected, and they appear to confine themselves almost entirely to the ice-field at some distance from the shore, only coming in to the land when driven by hunger. During the whole of our stay at the station

along

we knew of not more than eleven or twelve being taken, and they were killed by the Eskimos. Our party frequently saw bear-tracks on the ice, but nobody as much as saw a living bear except Lieutenant Ray, who had the good fortune to catch a glimpse of one as he made his escape into the moving ice pursued by all the dogs and half the men and women of the village.

The bears seemed generally anxious to escape when they encountered men and dogs. Only

one or two showed fight or came to bay.

Bears were wandering about the ice all the year round, as the natives occasionally reported them, and twice during the winter of 1882-83, impelled by hunger, they came holdly into the village, once at night and once in broad daylight, and made an attack on somebody's storehouse of seal-meat. Of course the natives immediately turned out and killed the bear.

Towards the end of April, 1883, a native who belonged at the Point Barrow village, when returning from the spring deer-hunt, met a she-bear and her cub, some 20 miles inland, at the point where the Eskimo trail crosses the river Kuaru, and killed them both. We obtained their

skins by purchase

The bears killed in winter were beautifully clean and white, but in summer they become exceedingly brown and dirty. One killed in August, 1883, was so dirty as to be almost black about the legs.

### 8. PHOCA VITULINA Linn.

### HARBOR SEAL. (Kasigia).

The Harbor Seal is well known to the Eskimos, who have several skins of this species among their "pokes" or floats for whaling. They said that they occasionally captured it at Pergniak in Elson Bay, and down the coast at Wainwright's Inlet, where it is said to "haul out" on land.

This species is represented in our collection by a single skull brought in for sale by a native, by did not know where it came from.

### 9. PHOCA FŒTIDA Fabricius.

### RINGED SEAL (Nětuř).

Từ xgiữi, old stinking male: Ninhq, temale: Netyia ru, young of the year.

This is the only seal that is at all common at Point Barrow, and is the main staple of food of the Eskimos. It remains the whole year through, and is to be found anywhere in the icefield that there are sufficient cracks for it to find a breathing place.

They especially affect the ice, and consequently are rarely to be seen in summer, when the sea is clear of ice. When, however, there is much loose ice running, seals are always to be found in plenty, and are captured by the Eskimos from their *umiaks* with rifle and harpoon. They occasionally come into the shoal water of Elson Bay in the summer, and are taken in nets set along the shoare.

When the ice comes in and the sea begins to freeze over in October they become quite abundant, haunting the open pools in the pack and making breathing-holes (adlu) in the "young ice." At this season the natives take them entirely with the rifle and harpoon, either shooting them as they swim in the open pools, and darting a harpoon into them before they sink, or else watching at the breathing-hole with the rifle and stabbing-harpoon.

As the season advasces into November and December and the sun disappears, so that there are only a few hours of daylight, the seal-netting begins. This can only be carried on in the darkest nights when there is no moon. The natives say that even a bright aurora interferes with their success.

At this season of the year there are very often large temporary cracks in the ice-field a mile or two from the shore, which remain open for several days at a time, and are a great haunt of the seals. When such a crack is discovered the hunters from the village turn out in force, and skirt along the edge of the crack till they find a suitable place for setting their nets.

They select a place where the ice is level and not too thick for about a hundred yards from the edge of the crack and then proceed with their ice-picks to cut three holes parallel to the crack. The middle hole is large enough to admit the passage of a seal, and the other two are smaller and serve to allow the stretching lines of the net to pass through. They are about five yards, the length of the net, apart. The stretching lines are let down through these holes, and grappled and drawn up through the center hole with a long slender hooked pole. They are then attached to the upper corners of the net, which is thus drawn down through the middle hole and hangs like a curtain underneath the ice. The end-lines are loosely fastened to lumps of ice, and the hunter sitting down near the net begins to rattle on the ice with the butt of his pick, scratch with a little tool made of seals' claws mounted on a wooden handle, whistle softly, or make some continuous gentle noise which excites the curiosity of the seals, who are swimming round in the open water.

These come swimming in under the ice in the direction of the sound and of course come in contact with the net, which, hanging loosely, soon completely entangles them. The running out of the end-lines warns the hunter that there is a sea! in the net, and when he thinks it is sufficiently entangled, he banks it up through the middle hole by means of a line attached to the middle of the net. The seal is frequently drowned by the time it is hauled up, but sometimes has to be killed by bending the head back sharply so as to break the neck.

After disentangling his catch, the hunter sets his net again and waits for another seal. I have known a single hunter to catch as many as thirty seals in the course of one night. The dead seals of course freeze stiff very rapidly, and if there is snow enough on the surface of the ice, they are stacked up, by sticking them up on their tails in the snow to prevent their being snowed over, until they can be brought in by the dog-sleds.

When there is no suitable water for netting on a large scale, the natives are constantly on the watch for small cracks and breathing-holes, where the scals come regularly. Two or three men will surround such a place with four or five nets, so that every scal that comes to the hole is sure to be caught. These nets are kept permanently set and are visited every day or two.

Later in the season when the sun has returned, and the hunters find regularly established breathing-holes in the ice-field, the nets are stretched that across the holes by cutting four holes round the *adla*, and stretching the corners of the net out to these. Each hunter will have several nets set in this way and will yisit them every day or two.

When the "leads" of water open off shore in April, seals are always quite abundant there and the whaling umiuks usually catch a good many. They continue abundant all through the whaling season. Towards the end of June and through the month of July, when the ice, especially the level ice inshore, is growing rotten and wearing into holes, they begin to come up through these holes to sleep on the ice. They sleep however with extreme caution, waking up and raising their heads to see if all is safe every four or five minutes. They are so exceedingly shy at this season of the year that none of us ever succeeded in getting within decent rifle shot of one of them.

There is considerable variation in the color of this species. Individuals were seen which were almost white, being quite unspotted on the belly, and there was a complete gradation from these to specimens like one noted on January 7, 1883, of which the following is a description:

Ground color, black, belly no lighter than the back. Marked all over with ring-like, sometimes 8-shaped spots, white, numerous on the back, large and scattered on the belly, small and thickly crowded on the upper breast and throat. Flippers and claws very black.

### 10. ERIGNATHUS DARBATUS (Fabricius) Gill.

### BEARDED SEAL (U'g'ru.)

This species is far less common than the preceding (P. fatida), but is by no means rare, occurning even during the winter when the ice is broken.

They are also occasionally killed at the "leads" of open water during the spring whaling, but are most abundant during the summa, and autumn when the loose ice is running with the current, swimming around among the broken floes, and occasionally crawling out upon a cake to sleep. They almost invariably sink when shot at this season. Early in the season they are frequently

lor

seen close in shore, especially where there is open water between the shore and the "land floe" or "barrier."

The Eskimos pursue them in their *umiaks* with the rifle and walrus-harpoon provided with a short line and scal-skin floats, but did not capture many during our stay at the station. The skins are very highly prized for making *umiak*-covers, as they make a very fine and durable hide which is beautifully white. It takes six good-sized ug'ru-sking to cover one *umiak*. The Eide is also used for making walrus-lines and also for boot-soles when whitewhale skin cannot be obtained.

#### 11. HISTRIOPHOCA FASCIATA (Zimm.) Gill.

### RIBBON SEAL (Kaixo'lĭñ).

This is the first record of this species north of Bering Strait, but it can hardly be considered as anything more than a straggler of somewhat regular occurrence at Point Barrow.

It is, however, well known to the natives, who call it by a name which bears a striking resemblance to the names "Karoluk" and "Kioluk," which the natives of Pond's Bay and Cumberland Inlet apply to *Phoca granlandica*, which animal would hardly be distinguished from this species by the Eskimos.

The only individual we saw was a finely marked male, taken in a seal-net close to the villago at Cape Smythe, November 21, 1881. Unfortunately, we knew nothing of the capture until several days afterward, when the hunter brought the skin over for sale. He had mutilated it by cutting off the nose and flippers, and we were unable to procure the skull.

We heard of no more till the end of November, 1882, when a native reported that he had killed one at a breathing hole, but that it was carried away by the current. None were seen at any of the great catches of *Phoca factida* during the winter of 1882, although all the natives, both at Cape Smythe and Point Barrow, were especially on the lookout for them.

This species must be more abundant than is generally supposed on the Siberian coast of Bering Sea. Their skins are frequently to be seen among the seal-skin clothing worn by the American whalemen, which is procured at Plover Bay, Indian Point, and other places on the Siberian coast.

### 12. ODOBÆNUS OBESUS (III.) Allen.

#### PACIFIC WALRUS (Albreûk).

Walruses are of rather frequent occurrence off Point Barrow during the season of open or partially open water, but are never very abundant.

In the spring of 1882, one or two were reported by the natives as early as the end of May, out at the "lead" of open water, but in 1883 they were very much later. We heard of none antil July 3, when many old bulls were reported to be traveling up to the northeast at the "lead."

During the summer herds are occasionally seen swimming among the broken ice outside of the barrier, or asleep on a large cake.

They were quite plenty during the month of September, 1882, when there was much heavy loose ice from one to three miles off shore, moving rapidly with the current to the northeast. Many herds and solitary walruses floated up past the station on cakes of ice. We saw none returning, and none were seen or reported after September 28.

They were rather more plenty outside the land-floe in 1883 than they had been the preceding season, and the Eskimos had taken about a dozen up to the middle of August, pursuing them with the rifle and harpoon in their umiaks.

During the autumn of 1881 the ice was a very long distance off from the shore, and consequently there were no walruses. On October 17, while the sea was still open, three walruses came swimming in towards the land close to the station. They appeared fatigued, as if they had come a long distance, and evidently wished to land on the beach, but were frightened away by the natives.

The whalemen complain very much of the increasing scarcity of walrus on their usual walrus-hunting grounds, the ice-field just north of Bering Strait. Where they were formerly accustomed to get a hundred walrus a day by shooting on the ice, they now consider eighteen a good day's

work. Not only have the walruses been killed off by the indiscriminate slaughter which has been the custom, but they have grown cautious, and have learned to withdraw to inaccessible parts of the ice fields, where they cannot be reached with a boat. This habit will go a good way towards preserving the species from utter extinction.

There seems to be some diversity of opinion as to the ferocity of the Pacific Walrus. Capt. E. P. Herendeen, who has killed a great many walruses, especially when "hauled out" on the land, insists that he never saw one show fight, that they are only anxious to escape from their pursuers, and that the chase is attended with no danger, except sometimes from the blundering efforts of the animals to escape.

Capt. L. C. Owen, on the other hand, one of the veterans of the whaling fleet, who commanded the first steam whaler in the Arctic, and who has probably had as much experience as any one in shooting walruses on the ice, asserts that he has frequently been attacked by wounded walruses, and that his "dinghy" or walrus-bout has often he in reat danger from their "pecking" at it, as he expressed it, with their tush.

### 13. OVIBOS MCSOSATUA (Cmel.) Blainv.

### MUSK Ox (Umiñ man)

A skull of this animal was brought in by one of the trading parties from the eastward, just as we were getting ready to abandon the station. In the hurry and excitement of the time, we neglected to find out more accurately the locality from which it came. The party had been as far east as the mouth of the Colville, and the skull may have been brought from there.

The natives knew the animal well, and called it by nearly the same name as the eastern Eskimos, but none had ever seen it alive.

The skull obtained appeared very old and much weathered.

### 14. OVIS MONTANA (?) Cuv

### MOUNTAIN SHEEP; BIGHORN (I'mnea).

The Eskimos had many implements, especially water dippers, made of Mountain Sheep horn, and there were a good many garments made of the skin which is especially used for trimming decreakin clothes.

Most of the horns and the skins were obtained by trade from the natives to the east and south. The Point Barrow natives were, however, well acquainted with the animal, and several of them said that they had killed them, a great way off to the eastward, in very high broken land (Romanzoff Mountains?).

I have called the species Ovis montana (!), because there is a question as to the species of Mountain Sheep inhabiting Alaska, and we obtained no specimen that could be identified.

### 15. RANGIFER TARANDUS GRŒNLANDICUS (Kerr).

### REINDEER (Tù'ktu).

 $P\hat{a}^*$ änää, duck with large antlers;  $Na^*la$ , yearling buck;  $K\hat{a}^*lanää$ , don: Ainää, etc. pornels: doe; Noxa, faws.

Reindeer do not come down to the coast near Point Barrow in any large numbers. Straggling individuals and small parties are occasionally to be seen during the summer, wandering around the tundra and sometimes come down to the beach and the lagoons, especially on calm, sunny days when the flies are troublesome.

Large berds have been seen down the coast, 25 or 30 miles from the station, and near the mouths of the rivers at the east, but only stragglers reach the Point.

During the rutting season, in the latter part of October, a good many are to be seen roaming round a few miles inland, though they are very wild. The rutting backs, however, are rather inclined to be curious and to come towards a man if he keeps perfectly still. Later in the winter,

from January on, they were continually seen and reported, and their tracks and the places where they had scraped away the snow to get at the moss were frequently seen.

The natives from the village go out on snow-shoes to hunt them, and when a herd of deer is seen the hunter moves straight towards them at a rapid pace. When the deer begin to run the hunter runs after them as fast as he can, trying to keep them in sight. His pertinacity is generally too much for the curiosity of the deer, and in a short time one or more of them will usually swerve from the line of flight and gradually circle back to see what this is that is following them.

The hunter generally opens fire as soon as the deer gets within five or six hundred yards and keeps it up till be either kills the deer or frightens it out of range. Strange as it may seem, a good many deer are obtained in this way. The natives are very lavish of their ammunition, and by their reckless shooting have rendered the deer very wild.

Most of the deer obtained by the natives, however, are killed along the valleys of the large rivers, Kuaru, Meade River, and Ikpikpung, which empty into the Arctic Ocean east of Point Barrow.

Many of the natives go in to these rivers, 50 to 100 miles to the south and southeast, as soon as eneigh snow has fallen to make sledging practicable, and there is easin camped in snow huts until the days grow too short for hunting. At this season the deer are quite plenty in this region, and go in large herds. Captain Herendeen describes the alluvial rists of Sicade River as "looking like a cattle-yard" from their tracks.

The Eskimos seem to be of the opinion that most of the decodes, each this region and go further inland when the winter night sets in returning about the first of Patagary.

The great season for deer hunting is in the months of February and March. With the return of the sun, about the last week in January, most of the native of both villages start off for the rivers, and are to be found camped in small parties, consisting of two or three families, over a large extent of country. They stay until the end of March, or sometimes as late as the middle of April, and secure a good many deer.

Two men who were hunting for the station in the spring of 1883 killed upwards of ninety, while they were out. Most of these deer are shot with the rifle, but a few are still taken in pitfalls dug in the snow-drifts, as described by Captain Maguire, of the English depot-ship Plover, in his report of his first winter at Point Barrow, 1852-253.

A female killed January 30, 1883, contained a focus about six inches long. Large numbers of well-developed embryos are brought in from the spring deer-hunt by the natives, who consider them a great delicacy. They are also very fond of the contents of the rectum.

#### 16. ELEPHAS ! sp.

### MAMMOTH (Kili'g'wa).

Much fossil ivory in a badly decayed condition is found on the sandbars of Meade River, and the natives have a good many implements of a much better quality of ivory. This, however, was probably obtained from the Nunatangment.

The natives had many stories about bones of the Kiligra, "the great dead reindeer"; "there are no longer any more on earth, only their bones remain." We endeavored to get some of the hunting parties to bring us in some of these bones, but we did not succeed in obtaining any.

### 17. BELUGA sp.

### WHITE WHALE (Kilëlyua).

White Whales were never very plenty near the station, but large schools occasionally passed up within sight of the shore during the season of open water.

A school of a hundred or more passed up within 200 yards of the beach September 28, 1881, and then turned and weat back again. There were many gray individuals in this school.

The whaling umiaks captured one or two each season we were at the station, and each year as soon as there was open water between the land-floe and the beach a large herd passed up to the northeast.

About a week or ten days later another large herd of several hundred passed up each season, and these were all that were seen.

The last herd in 1882 came close to the beach, and one was killed with a rifle. There was no opportunity to make a careful study of it or to obtain its complete skeleton, as it was immediately cut up for meat. The skull was unfortunately destroyed by the ice while being cleaned in the water by the sand-fleas.

The following are the measurements of this specimen:

#### ADULT REMALE.

From fork of tail to tip of lower jaw		Inches.
Girth behind dippers		4
Breadth of tail		$6\frac{1}{3}$
Breadth between angle of lower jaw	. 1	0
Length of head from ear	. 1	4
Length of vulva		10
Length of Supper		3

Color, white, grayish on flukes and flippers, with a yellowish tinge on the back; mamma opposite the lower third of the genital sulcus, which includes the anus; mammary sulcus about two inches long; blubber thick.

These animals are much prized by the natives, who value the skin very highly for making the finest quality of water-proof soles for their seal-skin boots. They are also sometimes used for making very fine walrus or whale lines.

The flesh is quite palatable, though rather tasteless.

### 18. MONODON MONOCEROS Linn.

### NARWHAL (Tugáliñ).

No living Narwhals were seen during our stay at Point Barrow, but we found the ivory in the possession of the natives. They recognized drawings of the anime's, and said that they were occasionally seen and killed. The name is essentially the same as one of those applied by the Greenlanders and eastern Eskimos to this animal.

#### 19. ORCA sp.

#### KILLER (A'alo).

The natives described a whale which they sometimes saw, and which was "bad" and had large teeth. From the resemblance of the name to the ordinary Eskimo word for "Killer" I am inclined to believe that a species of *Orca* was meant. None were seen during our stay at the station.

### 20. BALÆNA MYSTICETUS Linn

### POLAR WHALE, "BOWHEAD" (A'k' bicûk).

Whales' jawbones, skulls, and vertebre are plenty—scattered along the shore and in the villages, where jawbones and ribs are used for staging timbers, and they are also sometimes found buried in the turf, indicating considerable age. There is also much decaying whalebone in the ruined iglus which have been laid open by the sea at Cape Smythe, pointing to the time when whalebone had no commercial value, and more was obtained than could be used for ordinary purposes in the village.

About the middle of April, when the "leads" of open water begin to form off shore, the whales appear—a few stragglers at first, but gradually increasing in numbers—all traveling to the northeast even when the lead is much clogged with loose ice. Indeed, the whales seem to have learned that they are much safer in the ice than in the open water, and may be heard "blowing" in the loose pack when there is plenty of open water for them to travel in.

The "run" lasts until about the 1st of July, after which, during the season of open water, there are no whales until about the middle or end of August, when they begin to "come out," as the whalemen say, generally moving back at some distance from the shore.

The whaling fleet generally eatch a few whales in Bering Strait and outside of the ice early in the season, when they first come into the Arctic. They then endeavor to reach Point Barrow

by the middle or end of July so as to meet the whales when they come out.

Some ships work as far to the eastward of the point as the ice will permit and follow the whales out. Many whales were taken in 1882 between Point Barrow and Return Reef. Other ships, if the whales do not appear soon after their reaching the point, turn back and go off to the western whaling in the neighborhood of Herald Island. The fall whaling is carried on as late as the ice will permit. In 1882 some of the ships staid in the neighborhood of Point Barrow until nearly the end of September.

The season of 1883 was very unfavorable for the whaling fleet. The ships were unable to get any distance cast of the point, and although whales had been plenty in the spring migrations they did not begin to come out till the end of August, and then in comparatively small numbers.

None of the ships accomplished much.

The natives pursue the whales during the spring migrations, hauling their boats on sleds across the rough ice to the open water. About twenty unitaks, carrying each a crew of from eight to ten men, are fitted out for whaling from the two villages, and when there is open water and any prospect of whales they spend all the time out at the edge of the "lead" on the lookout for whales while the women travel backwards and forwards with their food.

Each boat is supplied with several harpoons, to each of which is attached a short line and a pair of floats made of inflated seal-skins, and they endeavor to get so many of these floats fastened to the whale that he can no longer sink, when they paddle up and dispatch him. They formerly used stone-headed lances for this purpose, but are all now provided with regular steel whale lances, and many of them also have bomb-guns which they have bought of the whalemen or obtained from wrecks.

They have also plenty of iron harpoons of the best pattern, but it was decided in 1883 that they would have no luck in whaling unless the first harpoon darted at the whales was of the old-fashioned stone-headed kind, such as their grandfathers killed so many whales with.

When the "lead" of water is narrow the whales are sometimes shot with a bomb-gun from the edge of the ice.

As soon as a whale is killed it is towed to the edge of the solid ice-floe, and there all hands—men, women, and children—go to work at once with "spades" and knives to cut off all the blubber and meat they can get at. The whale frequently sinks or is carried off by the current under the ice before they have succeeded in saving more than a portion of the blubber. Every one is entitled to all he can get of the blubber and "blackskin," but the whalebone (shukuk), which is the great staple of trade with the white men, is portioned out according to a regular rule. The crews of all the umiaks that were in sight at the time the whale was struck have an equal share of the whalebone.

The "blackskin" mentioned above, which is the epidermis of the whale, and has been very often described, is considered as great a delicacy by these natives as it is by the eastern Eskimos. They would go anywhere or do anything to secure a feast of "muktuk," as they call it.

It is the custom on most whaleships, when "boiling out" near shore, to allow the natives to come on board and cut off the blackskin, provided they do not take off too much blubber with it, and I have seen boat-loads carried off from one ship. They are also very fond of the tough, white gum round the roots of the whalebone, which goes by the name of "mum-ma." These are almost invariably eaten raw, for very few Eskimos would be able to wait for their muktuk to be cooked.

They are not very expert or very bold in their whaling, and consequently do not capture many whales. Only three were killed in the two seasons we were there. Capt. L. C. Owen, however, informs me that one season ten whales were taken by the boats of the two villages.

In speaking of whales to the white men the Eskimos call them Pw'ahi, which is an attempt to pronounce the word "Bowhead."

The stripped curense of a female which drifted ashore September 1, 1882, was found to contain a feetus about three feet long.

#### 21. SOREX PORSTERI Rich.

FORSTER'S SHREW MOUSE (Ug'ru'nû).

A little Shrew which was brought home in alcohol and identified as this species was brought in by a native who had been off to Meade River on the spring deer hant. This was the only one observed.

### 22. MYODES OBENSIS Brants.

TAWNY LEMMING (A'richād).

This species, like the succeeding, though abundant around Point Barrow, is not equally plenty every season. We saw none in 1882, and none were brought in by the natives, who were in the habit of bringing in all sorts of birds and animals for sale.

None were obtained until June 11, 1883, when a good sized young one, probably born the year before, in full summer pelage, was picked up dead on the tundra. During the rest of June and in July they were often seen, and many were caught. Early in the season they were often found running in tunnels under snow-banks.

This species and the next make shallow burrows and galleries in the tussocks of turf on the tundra, and spend a good deal of time under ground.

A mother and seven blind young were taken June 27.

#### 23. CUNICULUS TORQUATUS (Pall.) Coues.

Hudson's Bay Lemming  $(A'rrit\bar{n}\hat{u})$ .

Like the last, this Lemming, though abundant, is not equally plenty every season. During the whole year of 1882 we did not see a single Lemming, although signs of them were very plenty. The tundra was completely riddled with their galleries and burrows, and we occasionally saw tracks on the snow or mud. Their droppings, besides, were very thick in many places on the tundra, and the numerous owl's castings scattered over the tundra were made up almost wholly of Lemmings' skulls, bones, and hair.

In 1883, the natives began to bring them in early in January, and all the rest of that season they were quite abundant. Their habits are quite the same as those of the Tawny Lemmings. In summer they are only to be seen when running from one gallery to another, and in winter their tracks generally lead to a burrow in the snow-bank.

They are seldom seen in winter, except during drifting snowstorms, when the snow over their tunnels is probably blown away. This has given rise to a curious fancy among the Eskimos, who say that in stormy weather they come down from the sky, whirling around and running around in spirals as soon as they touch the ground. The first one we obtained was brought in, during a violent snowstorm, by a native, who informed us, "There are none here on the land. As it was bad weather he fell down from above." This superstition is interesting in connection with the notion of the Norwegians that the great hordes of Norway Lemmings come down from the clouds,

They appeared to be spread over a pretty wide extent of country in 1883, as we obtained specimens from near the station and from various deer-hunters' camps in the interior.

Up to April all the specimens taken were in winter pelage, but none of them were completely whit—all showing faint rufous spots indicating the position of the ears, and usually more or less rufous suffusion on the back. The white, moreover, has a grayish cast, due to the fact, probably, that the tips of the hairs only are white, while the rest is a slaty gray. One specimen, taken in February, and, from its size, probably a young one of the preceding year, is much marked with gray and brownish on the back of the head and nape and between the shoulders. It has well-marked rufous car-spots. A specimen taken in April can hardly be distinguished from this, though a little larger.

Specimens taken towards the end of April and in May show considerable darkening on the back and much rufous on the sides, but we obtained none like those in the National Muscum, which show the winter-coat partly shed, exposing the shorter bright-colored summer dress.

All June specimens were in full summer pelage.

### 24. SPEPMOPHILUS EMPETRA (Pall.) Allen.

PARRY'S SPERMOPHILE (SPhsin).

This is only a straggler anywhere near the station, though the whalemen, who are in the habit of landing at Woody Inlet for wood and water, report it abundant in the neighborhood. The natives are well acquainted with it.

We first noticed its tracks in the snow in May, 1883, and a single rutting male was killed running about on the high banks below Cape Smythe.

### 25. LEPUS TIMIDUS ARCTICUS Allen.

POLAR HARE.

There were absolutely none near the station, and the natives were unacquainted with the animals. Capt. E. P. Herendeen, however, reports seeing traces of hares among the willows on Meade River in March, 1882.

Just as we were on the point of abandoning the station in August, 1883, a party of Nunatangmeun Eskimos brought in half a dozen roughly-prepared skins of this species, showing the occurrence of the animals somewhere in the Colville region.

### II.-BIRDS.

By John Murdoch, A. M., Sergeant Signal Corps, United States Army.

The birds and eggs brought home by the expedition were collected, with a few exceptions, within a circle of fifteen miles from the station, and, it is believed, give a tolerably complete representation of the bird-fauna of this limited region. This it will be seen is arctic in its character, with the addition of a few species like *Somateria v-nigra*, peculiar to the western parts of the continent. The range of a few species heretofore recorded only from the eastern part of the continent has been found to extend to this point.

The country in this region is a low slightly rolling tundra, interspersed with higher and drier patches, and covered with lakes and ponds of all sizes, sometimes connected by insignificant streams. The lower portions of the tundra are wet and marshy, and thickly covered with grass. On the higher portions the covering of grass is more scanty and the ground often bare, muddy, and black, partly covered with black and white mosses and lichens.

This we were in the habit of calling the "black tundra," and it was the special breeding-ground of certain species of birds, for example the Golden Plover, while others were to be sought for in the marshy lowlands, and others again on the dry grassy banks.

The birds breeding in this region are two or three species of land-birds and most of the waders. The great majority of the water-birds, the ducks, gulls, &c., pass on to more favorable breeding-sites on the sandy islands fringing the northern shore of the continent, and on the banks of the great rivers running into the Arctic Ocean east of Point Barrow.

Most of the birds and eggs were collected by the writer and Sergeant Middleton Smith, though valuable additions to the collections were made by Lieutenant Ray, Captain Herendeen, and other members of the party.

The nomenclature employed is that of Ridgway's Catalogue (Bull, U. S. Nat. Museum, No. 21, 1881), to which the numbers refer, and the Eskimo names have been appended wherever possible.

### [21.] SAXICOLA CENANTHE (Linn.) Bechst.

#### STONECHAT (Sú'ksaxia).

As Mr. Nelson remarks, this species appears to be very erratic in its occurrence in Northern Alaska, being quite common some seasons and wholly absent the next.

Early in the spring migrations of 1882 we had these birds in comparative abundance near the station for a few days, but none remained to breed, and in the season of 1883, though a careful lookout was kept for them, not a single one was noticed.

Curiously enough, this alternation of seasons appears to have held good for the two preceding years. In 1880 Dr. Bean found them not uncommon from Kotzebue Sound to Cape Lisburne, while Mr. Nelson, visiting the same region the following season, failed to find a single individual.

The first one seen was taken May 19, 1882, when very little of the snow had melted and there were but a few patches of bare ground near the coast. It was a male, and feeding on the bare grassy spots near the house, and was very shy. The stomach contained truch digested material.

For three days they were with us in considerable numbers, scattered along the edge of the tundra, not going far inland, and exceedingly shy. They appeared to be traveling towards the northeast. The sexual organs of the only female taken showed no signs of development, but a male was shot on the 22d with testes well enlarged.

After this date they disappeared completely, and were not seen again during the season, or in the return migrations.

The natives appeared unfamiliar with the bird, and gave it the name which we afterward found them to apply to the Redpolls, and, in fact, to all the little passerine birds, except the Snow-buntings and Lapland Longspurs.

#### 157. COTILE RIPARIA (Linn.) Boie.

#### BANK SWALLOW.

On the evening of July 29, 1882, we were surprised to see a swallow flying round the station, but unfortunately failed to secure it, and it went off up the beach.

Swallows were seen again on the 31st and on August 10 flying round the station and going off up the beach. The last time they were pretty well recognized as this species,

No more were seen alive, but early in September one was picked up on the beach dead and frozen, but unfortunately too much dried up for skinning. It was, however, preserved in alcohol and is the only representative of the species in our collection.

A party of natives, who were with us when the bird was picked up, failed to recognize it as anything they had ever seen before.

These birds were undoubtedly stragglers from the Yukon region, where they breed in great numbers, which, after the cares of raising their brood were over, had drifted carelessly further and further north, following the flies and the sunshine till they reached this extreme point.

### 178a. ÆGIOTHUS CANESCENS EXILIPES (Coues) Ridgw.

### WHITE-RUMPED REDPOLL (Sú'ksaxia).

This species appears to be not common, and rather irregular in its occurrence at Point Barrow. Early in June, 1882, the natives spoke of seeing Súksaxia and promised to secure them for us. Accordingly on the 13th a lad brought in three eggs with the female, snared on the nest.

These were the only eggs secured, and we obtained or saw very few birds. Those that were seen appeared to have a preference for the muddy banks and gullies of the "black tundra," and the neighborhood of the village. None were noticed after July 3, and none were seen or reported in the season of 1883.

The season of 1881 must have been one of unusual abundance for this bird, as Mr. Nelson (Arctic Cruise of the Revenue Steamer Corwin, 1881) speaks of finding it one of the commonest birds at Point Barrow. It certainly was not common in 1882. Nor did \*\*Legiothus linaria\*, which he speaks of finding in the same localities, occur at all in either of the two seasons that our station was occupied.

#### 186. PLECTROPHANES NIVALIS (Linn.) Meyer.

#### Snow-bunting (Amau'liga).

This and the next species were our commonest passerine birds; in fact, the only ones which could be said to be at all common.

Our first warning of spring, before the snow had fairly begun to show signs of melting, was always the appearance of the little *Amauliga* hopping and twittering around the wind-blown spots and the cook's refuse heap, a little explorer, come on to spy out the land far ahead of the main body of the migration.

In 1882 the first Snow-bunting and the first bird of the year, a male in full breeding plumage, appeared on Easter Sunday, April 9, a pleasant and warm day for the season. The snow had not really begun to melt, but the ground had blown bare near the house and there had perhaps been a little melting on the sunny side of the hillocks, where the little fellow was running and picking.

H. Ex. 44---14

They were a little later the next season. The natives reported seeing one or two at Point Barrow April 16, but we saw none near the station till the 19th. Stragglers continued to arrive through April and May, but they were not really plenty either season till about May 20.

They began to sing about the middle of May, and by the 23d or 24th were well established and in full song.

Three or four pairs made their home near the station, and several more in the village, while the rest were scattered along the edge of the tundra, but few going any distance inland. They especially affected the broken muddy banks and gullies below the village and along the shore of the lagoons, and the cook's refuse heap was from the first a great attraction.

The males spend a great deal of time singing perched on the highest point they can find. The ridge-poles of our buildings and the wind-vane were favorite resorts for these jolly little singers. They continued singing until about the first week in July.

Early in June they begin to build in holes and erevices in the banks, where the nest is always completely concealed, vaising occasionally, at any rate; two broads in the season. The full complement of eggs appears to be six, though I found one nest containing seven eggs in 1883.

In 1882 one pair established themselves in a hogshead of bricks close to the station, unfortunately too much exposed to the curiosity of the Eskimo children, who caught and killed the male bird just as the female had completed her full set of eggs. Of course under the circumstances the nest and eggs were added to our collection. Nothing daunted, the female immediately secured another mate and went to work on a new nest, but was again doomed to disappointment, for when she had finished her second nest and laid two eggs she was again robbed by the natives. We succeeded, however, in protecting the third nest, and the young hatched and were beginning to fly by the end of July, by which time earlier broods were already pretty well grown. During the early part of July, after the males have ceased singing, they keep together in broods, and keep pretty well out of sight, as they are beginning to moult and take on the fall plumage. About July 25, however, they appear in considerable numbers, mostly young of the year in the gray plamage, associating with the young Longspurs around the empty village and about the native camps. They continue quite abundant in large loose flocks, generally through August, gradually becoming scarcer in September. The last one was seen in 1882, on September 20. We left them still comparatively plenty when we abandoned the station in 1883.

### 187. CENTROPF ANES LAPPONICUS (Linn.) Caban.

### LAPLAND LONGSPUR (Nessaúdliga).

The Longspurs, though, if anything, more abundant than the last species, arrive later and depart earlier. They arrived both seasons at very nearly the same date, and were equally abundant.

On May 20, 1882, which was a comparatively warm day with a fresh southwest wind, they suddenly appeared in considerable numbers, having probably arrived during the night, apparently all males, in full song.

They were to be found on all the bare spots on the tundra, near the station, along the coast, and near the cemetery at the head of the lagoon. Several were secured, and their stomachs were found to contain beetles. The sexual organs were fully developed. They were rather less abundant tarly in the season of 1883, as there was much less bare ground than the year before at the time of their arrival, May 21.

Though abundant a short distance inland, these birds were seldom seen around the station or along the edges of the beach and the lagoons, like the Snow-buntings. In accordance with what appears to be their general hubit elsewhere, they are specially to be looked for on the higher and drier parts of the tundra, where the nest is built in the grass, and not concealed in holes or crevices, like those of the snow-buntings.

During the breeding season, that is, from the time of their arrival till July 1, the males keep up a continual song, frequently soaring up and singing in the air like a bobolink. Their note at other times is a metallic chirp, not unlike that of the Titlark.

Notwithstanding the lateness of the season in 1883, a complete set of six eggs, already showing signs of incubation, was found on June 6, a week earlier than in 1882. This nest was the only one

found on a mud-bank, and partially concealed by a clod, though not so completely as a Snow-hunting's nest would have been. They appear to raise sometimes two broads in a season, as a nest has been found as late as Jane 21 containing only two eggs. We never found more than six eggs in any nest of this species, and sets of five were frequently found far advanced in incubation.

The first newly-hatched young were noticed about the middle of June. Like the Snow-buntings they keep themselves pretty well out of sight during the first half of July, but from then through August appear in considerable numbers, congregating with the Snow-buntings round the village and native camps. The young, seme of which are fully fledged by the middle of July, gather in large loose flocks, and appear to remain later than the adults. They go off gradually near the latter part of August, and were last seen in 1882 on the 4th of September. We left them still quite abundant in 1883, when we abandoned the station.

### 207a. ZONOTRICHIA GAMBELI INTERMEDIA Ridgy.

#### INTERMEDIATE WHITE-CROWNED SPARROW.

This bird, which is common in the Yukon region and on the lower Mackenzie, occurs at Poinz Barrow only as a straggler. A single individual, which Mr. Ridgway has identified as the young of the year of this species, was caught in one of the tents at the station September 11, 1883, a solitary instance to be compared with the northward autumnal wanderings of the Bank-swallows.

### 217. JUNCO HYEMALIS (Linn.) Sci

BLACK Snowbird (Sû'ksaria).

This is another straggler from the Yukon region and the wooded interior of Alaska, where Mr. Dall found it not uncommon during his stay at Nulato.

The solitary instance of its occurrence near Point Barrow was on May 24, 1883, when a male, apparently ready to breed, was taken not far from our station.

#### 406. NYCTEA SCANDIACA (Linn.) Newt,

SNOWY OWL (Ukpik).

This bird may be fairly considered a resident of these regions, although in the depths of the winter it recreats with the ptarmigan back to the "deer country," that is, the valleys of the large rivers running into the Arctic Ocean east of Point Barrow.

Its abundance in the spring and summer near the coast appears to depend on the presence or absence of its favorite food, the Lemming, as has been noted elsewhere by Mr. Nelson.

During the season of 1882 we saw no Lemmings, though signs of their presence in the shape of droppings, and their skulls and skeletons in owl's castings, were numerous all over the tundra. During that season we saw but very few owls. On the other hand, in 1883, Lemmings were exceedingly plenty all round the station, and owls were proportionately abundant; scarcely a day passed without one or more being seen sitting on the tundra, generally on the top of a bank or small knoll, on the lookout for Lemmings.

They were exceedingly shy and watchful, and, though seen and pursued nearly every day, only two were taken.

One of these made a regular habit of coming every afternoon at about the same time and settling himself in plain sight of the station on the opposite bank of the lagoon. For nine days he came regularly, and afforded much sport to several members of our party, who would go out regularly to capture him with rifle or shotgun, and as regularly return bailled. He was at last secured by two men, one of whom attracted his attention while the other managed to creep up within gunshot under cover of a bank.

These birds showed no signs of breeding while in our neighborhood. Some of the Eskimos said they could get the eggs from a camping-ground towards the southwest, but they failed to do so.

The only hawk obtained by the expedition has been identified by Mr. Ridgway as this form, and was taken at the station, where he had alighted on the flagstaff, in the autumn of 1882. Hawks were occasionally seen during both seasons, 1882 and 1883, but were always very wild and difficult to approach. Occasionally they were seen close enough to be recognized as Gy'' lcon<sub>2</sub>, probably of the same form as the one captured.

The natives say that they are abundant on the rivers flowing into the Arctic Ocean, where they feed on young wild-fowl and ptarmigan. They say they breed "umasiksu," "a long way off," One man said that he had seen the nest and eggs.

## 449. AQUILA CHRYSÆTUS CANADENSIS (Linn.) Ridgw.

GOLDEN EAGLE (Timminkpuk).

We never saw this bird alive during our stay at Point Barrow, and it is only included in this list because we obtained a native-made skin from some natives who went last summer to the east-ward of the Colville River, where they secured the bird.

There were one or two other skins in the two villages, where they were in great repute as talismans or charms for securing good luck in whaling. There were also many wing and tail feathers among the natives, who use them as ornaments to their fur jackets.

## 474. LAGOPUS ALBUS (Gm.) Aud

WILLOW PTARMIGAN (Aki'dagin).

This species is resident but never very plentiful. Tracks were always to be seen on the snow during the winter, but the birds themselves were less often seen, while they were frequently seen in pairs during the breeding season, though the nest was never found.

They were always wild and difficult of approach, so that comparatively few were obtained. They were found to be quite abundant among the willow shrubs inland along the rivers, and Lieutenant Ray found them numerous at the mouth of Meade River, May 1.

An occasional male begins to show traces of brown feathers about the head and neck as early as the first week in April, and the change is very gradual.

The last that was seen (July 10) still showed a considerable amount of white in the plumage, and it is possible that the change is never complete. The females taken all appeared more completely changed than the males.

We found the meat as tasteless and insipid as other observers have found it.

These birds in the fall were occasionally seen sitting on the broken ice along the beach.

## 475. LAGOPUS RUPESTRIS (Gm.) Leach.

ROCK PTARMIGAN (Akiddanin).

The Rock Ptarmigan is a much less plentiful resident than the foregoing, from which the natives do not distinguish it.

As far as we could judge its habits are the same. One or two were obtained, one a female, which had evidently bred not far from the station, though the nest was not found.

## 509. STREPSILAS INTERPRES (Linn.) Illig.

TURNSTONE (Tûlliqua).

This species was found to be decidedly scarce, both years, during the spring migrations and the breeding scasch. We occasionally saw one or two inland, but were unable to secure any till about the 10th or 12th of 2th; at which they appeared at Pergniak, straggling adults, who had finished breeding and were beginning to molt. Early in August, the young appeared in considerable

numbers along the coast, near the station and round the muddy puddles in the village, and were quite abundant for two or three weeks.

They were exceedingly tame, and for several nights in the middle of August, 1882, three or four came round the back door and the cook's refuse heap, making themselves perfectly at home, and allowing one to approach within a few feet of them before they took flight.

Towards the end of August they grew scarcer, and finally disappeared, in 1882, about the 30th. As the Black Turnstone (S. mclanocephala) is such a common bird in the Yukon region and south of Bering Strait generally, one would naturally expect to find it at Point Barrow, particularly as Mr. Nelson reports it from Wrangel Island. Nevertheless, during the two seasons of our stay at Point Barrow, we did not obtain the slightest evidence of its occurrence in the region.

### 513. SQUATAROLA HELVETICA (Linn.) Cuv.

BLACK-BELLIED PLOYER (Ki-raion),

This plover is quite rare. It was occasionally seen and heard in the season of 1882, but none were noticed the next summer, and none were secured.

The natives are perfectly familiar with the bird, and use the dried skins as amulets or talismans to secure good luck in deer-hunting.

Two such skins tied to a stick represent the species in our collection. The natives told us this bird would arrive later than the Golden Plovers, and this appeared to be the case.

### 515. CHARADRIUS DOMINICUS Mull.

AMERICAN GOLDEN PLOYER (Tu'dliñ.)

A large series of Golden Plovers collected at Point Barrow, where they are among the commonest waders, all proved upon careful examination, to belong to this species. It is probable that *C. dominicus fulcus* does not range so far north on the American coast.

OW

en

rly

he

le.

Indeed, Mr. Nelson's note of the occurrence of this form on Wrangel Island seems to me to be rather doubtful, as from his account the bird was only seen and not captured, rendering identification amost impossible.

They are among the earlier waders to arrive, as stragglers generally appear about the 20th to the 25th of May, before there is much bare ground. In 1882 a small party in full breeding plumage, and apparently all males, arrived May 21, but no more arrived until June 11. The fundra was at this time bare only along the edge of the beach, and the ice and snow was not yet gone from the lagoous.

This party remained in nearly the same place for a couple of week—feeding on small red worms which they found in marshy spots, and all but two of them were taken.—hough they were very wild.

Along through the first and second week in June they continue—arrive in small parties, and from that time on are quite plenty scattered in pairs and threes an over the tundra. They are very wild and difficult to approach, and very noisy. In addition to their ordinary well-known callnote, they have in the breeding season a loud but very melodious—y of "Tad'ling!" many times repeated, uttered as the bird flies along rather high, with long slow strokes of the wings.

They were evidently nesting both seasons before June 20, int neither season were we able to find the nest before the 22d or 23d. The nest is exceedingly hand to find, although it is not concealed at all, but is simply a depression in the bare black clayey tundra lined with a little dry moss. The only vegetation on this part of the tundra is white and grayish moss, which harmonizes so extraordinarily with the peculiar blotching of the eggs that it is almost impossible to see them unless one knows exactly where to look. A favorite nesting site is on the high banks of the gullies or small streams. No nests were ever found in the grass or in swampy ground.

The sitting birds show great solicitude when disturbed, feigning lameness, and trying to attract one away from the nest. They are shrewd enough always to keep quite a distance from the nest, as long as the collector is anywhere in the vicinity of it, and it is singly time wasted to attempt to find the nest by looking for it, as I know by hard experience. The only way to make sure of the

eggs is to withdraw some distance, and sit down patiently and wait for the bird to go back to her eggs, watching her if necessary with a field-glass. Having marked her on to the nest, one must walk towards it in a straight line, looking neither to the right nor the left and keeping his eyes fixed upon the spot she rises from. He is then pretty sure of the eggs. However, the surface of the tundra is so uniform that a careless glance to one side or the other after the bird is flushed may throw the collector wholly off the track, and then he has to go back and wait for the bird to return again.

to Mr.

Both males and females take a share in the incubation. In 1882 the sitting bird was frequently secured with the eggs, and in every case turned out to be a male; but in 1883 a number of sitting females were taken, and finally, in one or two cases, both parents were taken with the eggs, and both males and females had their breasts bare, as if incubating.

The nesting season continues till the first or middle of July, about which time the adults begin to collect in flocks, feeding together around the poads on the higher tundra, associated sometimes with a few Knots or a straggling Curlew.

The old birds leave for the south about the end of July, and no more Plovers are to be seen till about the middle of Angust, when the young, who heretofore have been keeping out of sight, scattered over the tundra, gather into flocks, and for several days are quite plenty on the dryer hills and banks, after which they depart. Stragglers may be seen up to the end of August.

## 528 a. MACRORHAMPHUS GRISEUS SCOLOPACEUS (Say) Coues.

## RED-BELLIED SNIPE; GREATER GRAY-BACK.

A few of these birds bred near the station, but they are decidedly rare during the breeding season. The young of the year, however, appear in large tlocks about the middle of August and stay for a few days about the small ponds on the tundra, especially on the high land below Cape Smythe.

At this season they are rather plenty, and when feeding associate with the young Dunlins and Grass-birds. They were much less abundant in 1883 than they were the previous season.

The nest was never found, although a pair were taken June 28, 1883, that were evidently nesting, as both had their breasts plucked and bare, showing that, as in the case of the Golden Plover, the male does his share of the work of incubation.

In the spring of 4882 a native boy brought in a female of this species, and what, he said, were the eggs. This was accepted without question at the time, although the eggs seemed rather small for the size of the bird.

A further acquaintance with the eggs of some of the smaller waders led to considerable doubt, which was justified by comparison of the set with authentic eggs of this species in the National Museum.

The eggs are certainly not those of this species, but closely resemble those of the Dunlin.

The bird appears but little known to the natives, and as usual in such cases we had various names applied to it. Many thought it was a Northern Phalarope (Sabrañna).

### 529. TRINGA CANUTUS Linn.

## KNOT; ROBIN SNIPE (Tha wia).

The Knot appears to be quite rare about Point Barrow. Only a few of the natives to whom one was shown recognized it and had a name for it.

In the season of 1883 only one was seen, appearing with a rather large flight of small waders. They were rather more abundant during the preceding season, and evidently bred somewhere in the vicinity, as a female was taken on July 11, with full-sized yolks in her ovaries. The nest, however, was never found.

The adults were not seen after July 5, and not one of the young appeared in the fleeks of young waders in the fall.

## 534. ACTODROMAS MACULATA (Vicil.) Coucs.

Pectoral Sandpiper (Aibwûkia = Walrus-bird).

Though this species is very common over the whole continent, and in fact over the greater part of the world, its eggs and breeding habits have hitherto been undescribed.\* We had the good fortune to find them breeding in considerable abundance in the neighborhood of the station, and were able to bring home a good series of authentic eggs.

It is one of the commonest of our waders, occurring all over the tundra in all sorts of situa-

tions, though never found on the beach.

us

There is frequently a great disparity of size between the two sexes. A comparison of the large series we collected shows that the average length of the female is about three-quarters of an inch less than that of the male, but that the smallest adult female was fully an inch and a half shorter than the largest male. The difference in size is so marked that the natives noticed it and insisted that the small females were not Aibwükia, but Nivilivilik (Ercunetes pusillus).

They arrive about the end of May or early in June, and frequent the small ponds and marshy portions of the tundra along the shore, sometimes associated with other small waders, especially with the Buff-breasted Sandpipers on the high banks of Nunava. Early in the season they are frequently in large-sized flocks feeding together around and in the Eskimo village at Cape Smythe,

but later become thoroughly scattered all over the tundra.

They begin pairing soon after their arrival, and are frequently to be seen chasing each other in the air with a loud chatter. The male has a curious habit at this season of the year. The skin of the throat is much distended and loaded with slimy fat, and can be puffed out like the throat of a ponter pigeon. During the breeding season, that is from the first of June to the first of July, the male may frequently be seen taking short, low flights, with the wings held high and beaten stiffly, while the throat is puffed out to its fullest extent, and the bird utters a most peculiar muffled hoot "hoo, hoo, hoo," many times repeated. There is something ventriloquial about the sound, which makes it seem as if uttered by some creata is a long distance off, and it was some time before we could be certain that it was the Pectoral Sandpipers that were making the noise. This hoot is only uttered on the wing as far as I was able to observe, though the males may be often seen to puff out their throats as they sit on the little knolls.

They get their native name "Aibicúkia," the "walrus bird," from this habit of swelling out their

throats, like "Aibwik," the walrus.

After the breeding season, they keep very quiet and retired, like the rest of the waders, and the adults appear to slip quietly away without collecting into flocks, as soon as the young are able to take care of themselves.

As soon as the young have assumed the complete fall plumage, that is about the 10th of August, they gather in large flocks with the other young waders, especially about the small ponds on the high land below Cape Smythe, and stay for several days before they take their departure for the south. Stray birds remain as late as the first week of September.

The nest is always built in the grass, with a decided preference for high and dry localities like the banks of gulleys and streams. It was sometimes placed at the edge of a small pool, but always in grass and in a dry place, never in the black clay and moss, like the Plover and Buff-breasted Scalpipers, or in the marsh, like the Phalaropes. The nest was like that of the other waders, a depression in the ground lined with a little dry grass.

All the complete sets of eggs we found contained four. The following is a description of the eggs, obtained from the examination of eighteen sets. They are pointedly pyriform like those of the other small waders.

\*Since the above was written, Mr. E. W. Nelson, formerly United States Signal Service observer at Saint Muchael's, Alaska, has published (Arck, Vol. I, No. 3, pp. 218-224) an excellent detailed account of the breeding habits of this species, as observed by him in the delta of the Yukon. His observations agree very onedy with our except that he observed the male bird "hooting" while on the ground. The observations of Dr. Adams, quoted by Mr. Nelson, had escaped my notice as well as his. The note, however, merely states that drawings made by Dr. Adams, and representing the male bird with his throat puffed out, were exhibited at a meeting of the Zoölogical Society, so that to Mr. Nelson belongs the credit of first making and publishing complete observations on the subject

The following measurements, in inches, indicate the size, shape, and limits of variation: 1.58 by 1.06; 1.44 by 1.11; 1.42 by 1.08; 1.54 by 1.02.

In color and markings they closely resemble the eggs of the other small waders. The ground color is drab, sometimes with a greenish tinge, though never so green as in the egg of P, alpina umericana and sometimes a pale bistre-brown. The markings are blotchings of clear umber brown, varying in intensity, thickest and sometimes confluent around the larger end, smaller and more scattered at the smaller end. Some of the eggs with brown ground are thickly blotched all over. A single egg in one set of four has the markings almost as fine as in A, hairdi, but the egg is larger and has not the characteristic ruddy line. All the eggs have the usual shell markings of pale purplish gray and light neutral tint.

the

The eggs may be distinguished from those of the Buff-breasted Sandpiper, which they closely resemble, by their warmer color.

Most of the eggs obtained were collected in 1883. The first nest was taken on June 20, a full set of eggs slightly incubated. Although eggs were found to contain large emoryos as early as June 28, perfectly fresh eggs were found July 6, and the last eggs brought in, July 12, contained only small embryos.

## 536. ACTODROMAS FUSCICOLLIS (Vieill.) Kidgw.

## Bonaparte's Sandpiper (Kai'aialu).

This is the first record of the occurrence of this species west of the Mackenzie River region, where McFarlane found it breeding, and it appears to be hardly more than a straggler at Point Barrow.

It was not observed in the spring of 1882, and an accident revealed its presence in 1883. A cust fired June 6 into a flock of Pectoral Sandpipers brought down one of these birds along with four or five of the other species.

After this, of course, a careful lookout was kept for this species, but only one other was seen, just a month later, alone on the tundra. The bird was also secured. Both were males and apparently breeding birds.

### 537. ACTODROMAS BAIRDI Coues.

## BAIRD'S SANDPIPER (Ai'bicâkia).

Though this little sandpiper is by no means uncommon, the natives seem to make no distinction between it and A. maculata, calling both by the same name.

They arrive about May 30, while there is still a good deal of snow remaining on the tundra, and are usually to be found along the edges of the pools at the top of the beach. After the tundra becomes clear of snow, they retreat back from the beach and are especially to be looked for on dry grassy portions of the tundra, particularly along the shores of our lagoon.

They are never very common and always solitary or in pairs, a quiet retiring little bird that never indulges in any of the conspicuous breeding antics noticed among the other waders,

The nest was always well hidden in the grass, and never placed in marshy ground or on the bare black parts of tundra, and consists merely of a slight depression in the ground thinly lined with dried grass. All the eggs we found were obtained from the last week in June to the first week of July, a trifle later than the other waders.

The sitting female when disturbed exhibits the greatest solicitude, running about with drooping outspread wings, and loud outcry, and uses every possible wile to attract the intruder from the eggs.

The nest is so well concealed, and forms so inconspicuous an object that the only practical way to secure the eggs is to withdraw to one side and allow the sitting bird to return, carefully marking where she alights. Having done this on one occasion and failing to find the eggs, after flushing the bird two or three times, I discovered that I had walked on the eggs, though I had been looking for them most carefully.

They leave after the breeding season in the same unobtrusive way that they have conducted themselves during all their stay, never collecting into flocks. We saw them occasionally during July.

### 539a PELIDNA ALPINA AMERICANA Cass.

## REDBACKED SANDPIPER (Mč'a-kapiā).

This species is common and breeds abundantly, although the nest is exceedingly hard to find, as the nesting birds are very wary and use every possible strategem to mislead one while looking for the eggs.

They arrive about the end of May. In 1882 they first appeared above the station in small flocks associating with the Golden Plovers, but the next spring the snow was slow in going off from this part of the tundra, and they were first noted below the village.

Some of them, perhaps, arrive paired, but the majority are pairing soon after their arrival, to judge by their actions. They scatter in pairs and threes all over the tundra, where there is still at this time a good deal of snow, and chase each other with much noise, taking wing suddenly without cause for alarm.

One will occasionally "set" his wings while in the air and soar for some distance, uttering a note quite different from the usual hoarse, rolling call.

As the tundra gradually clears of snow, they become more scattered and spread farther inland, deserting the shores of the beach lagoous, although they hardly confine themselves as much to the dry portions of the tundra as the Baird's Sandpipers are in the habit of doing.

Their rolling call through June is to be heard all day and every day, and reminds one of the notes of the frogs in New England in spring. In fact, some members of the party came home the first spring convinced that they had heard the frogs piping.

The nest, which is like that of all the rest of the waders, is always placed in the grass, sometimes in dry and sometimes in rather swampy places, but never on the black tundra or on the isthmuses between the ponds like the Phalaropes.

The eggs were first described from the Mackenzie region, by Richardson (Fauna Boreali-Americana, II, 383), but appear to be still little known in collections.

Both parents share in the work of incubation, though we happered to obtain more males than females with the eggs.

The young are pretty generally hatched by the first week in July, and both adults and young keep pretty well out of sight till the first of August, when they begin to show about the lagoons and occasionally about the beach, many of the young birds still downy about the head.

The autumn flight of young birds appears about the middle of August, associating with the young A. maculata and M. griscus scolopaceus, in good-sized flocks, particularly about the pools on the high tundra below Cape Smythe.

They continue plenty in these localities, sometimes appearing along the beach, for about a week, when the greater part of them depart, leaving only a few stragglers that stay till the first few days of September.

### 540. PELIDNA SUBARQUATA (Guld.) Cuv.

## CURLEW SANDPIPER.

The Curlew Sandpiper has never been before noted as occurring anywhere in America except upon the Atlantic coast, where it is a rare straggler.

I had the good fortune to capture a male in full breeding plumage, the only one seen, on June 6, 1883. It was in company with a good-sized flock of Actodromas maculata.

### 541. EREUNETES PUSILLUS (Linn.) Cass.

## SEMIPALMATED SANDPIPER (Niviliwiliak).

This species is a regular and fairly abundant fall visitor at Point Barrow, coming apparently from the east in large flocks.

None were seen either season during the spring migrations or the breeding season, but about the end of July they appeared in large numbers, arriving at Pergniak first and spreading down the coast.

Though a great many of them were shot, no adults were found either season.

## 544. LIMOSA LAPPONICA NOVÆ-ZEALANDIÆ Gray

## PACIFIC GODWIT.

This species, which is an abundant summer resident at the Yukon mouth and Saint Michael's, where it breeds, only occurs at Point Barrow as a straggler after the breeding season, appearing in August with the flocks of young Macrorhamphus, Pelidna, &c.

It is probably a quite regular though rare visitor, as we saw a few both in 1882 and 1883. Nevertheless, the natives appeared not well acquainted with the bird. Some called it "Tenstura" (Numerius barcalia), while others thought it was "Sabrana" (Lobipes hyperbores).

The two that were obtained were both young of the year.

This bird has not been previously recorded from the American coast north of Bering Strait,

## 356. TRYMGITES RUFESCENS (Vieill.) Caban.

# BUFF-BREASTED SANDPIPER (Núdluayu).

This is an abundant summer resident, and was more plenty in the season of 1883 than it was the year before.

They arrived both seasons in a body at about the same date (June 6 to 8), and were first seen on the dry banks below the village feeding greedily on the flies and beetles which were out sunning transcrives.

By the middle of June they had spread pretty well over the dryer parts of the tundra, both above and below the station. They were never seen on the lower marshy portions of the tundra, but always confined themselves to the high and dry banks, or what we called the black tundra.

The eggs, as might be inferred from their colors, are laid in the latter locality, as a rule, where they harmonize very well with the black and white of the ground and moss. We were unable to find the nest in 1882, but the next spring we collected the eggs in considerable abundance. Like the rest of the waders they build no nest, but deposit the four eggs, small end down, in a shallow depression in the ground lined with a little moss. Four is the usual number of eggs in a complete set, though we collected one set of five.

During the greater part of the breeding season, that is, from the time they arrive till the end of June, the males indulge in curious anties, which we had frequent opportunity of observing.

A favorite trick is to walk along with one wing stretched to its fullest extent and held high in the air. I have frequently seen solitary birds doing this apparently for their own amusement, when they had no spectators of their own kind. Two will occasionally meet and "spar" like fighting cocks for a few minutes and then rise together like "towering" birds, with legs hanging loose, for about thirty feet, then drifting off to leeward. A single bird will sometimes stretch himself up to his full height, spread his wings forward, and puff out his throat, making a sort of clucking noise, while one or two others stand by and apparently admire him. They are very silent, even during the breeding season. When they first arrive they are to be found associating with Actodromas maculata for a few days. After the breeding season they disappear gradually, never gathering into flocks, but quietly slipping away, and none are to be seen after the first week in August.

# 160. NUMENIUS BOREALIS (Forst.) Lath

### Eskimo Curlew (Turá turá),

This is a rather irregular summer visitor and by no means common, although well known to the natives. In the spring of 1882 it was the first wader to arrive, but in 1883 we saw none at all.

Two flocks of about twelve each arrived on May 20, when there was still much snow on the tundra and in the lagoons, moving up the beach towards the northeast.

No others were seen till the first week in July, when two were noticed, one associating with a flock of Golden Plovers and Knots. One taken at the time was already molting.

## 563. PHALAROPUS FULICARIUS (Linn.) Bp.

RED PHALAROPE (Salra).

One of the commonest birds, remaining till late in October, when the sea begins to close, They arrive early in June in considerable numbers, and already paired, in full breeding planage. As with Phalaropes generally, the female is the larger and brighter bird of the pair. We found it hard to make the natives believe that she was not the male. Dissection, actually showing the eggs in the ovary, was necessary before they would admit the fact.

The whole duty of raising and taking care of the broad after the eggs are laid, falls upon the males, who hatch the eggs and take care of the young broad, while the female spends her time away feeding. We never found a female sitting on eggs, or took one with her breast plucked. It

was invariably the male bird that was started off the eggs.

When these birds first arrive the sea is still closed, and the birds make themselves at home especially round the small ponds. As the snow melts away, they spread out over a greater extent of country, but never go far from the sea, and are always to be found in the wetter grassy portions of the tundra, particularly back of the beach lagoons, where they nest in large numbers.

The nest is always in the grass, never in the black or mossy portions of the tundra, and usually in a pretty wet situation, though a nest was occasionally found high and dry, in a place where the nest of the Pectoral Sandpiper would be looked for. A favorite nesting site was a narrow grassy isthmus between two of the shallow ponds. The nest is a very slight affair of dried grass and always well concealed.

Some of the pairs have their full complement of eggs laid by the middle of June, but others are much later, as fresh eggs were obtained as late as June 29, in 1882. Four is the usual num-

ber of eggs in a complete set, although sets of three incubated eggs are to be found.

They are exceedingly tame and attractive little birds during the breeding season, paddling about the little ponds on the tundra in their peculiarly graceful manner, having apparently no fear of man or beast, and keeping up a continual twittering, as if of conversation among themselves. They are at all times a noisy bird, especially when gathered into flocks.

They begin to collect in flocks, flying and lighting round the ponds, about the end of June, and continue in flocks through July, though as the sea opens they grow scarce, apparently roaming off inland, and out to sea. Late in July, when there were hardly any to be seen near the shore, I have found them 7 or 8 miles inland around the lakes in very large flocks, which were gradually assuming the gray winter plumage. The natives said that the Phalaropes went "south," which means "inland," and they would be plenty by and by. The adults appear to leave about the end of July, as the great flocks which stay so late in the fall seem to be all the young of the year.

These flocks come off the land about the first week in August, and are to be found along the shore and beach, occasionally feeding and swimming in the ponds back of the beach. Their abundance varies a great deal on different days, as they are apparently wandering back and forth a good deal from one feeding ground to another. They are apt to be specially abundant on days when there is much loose ice on and near the shore.

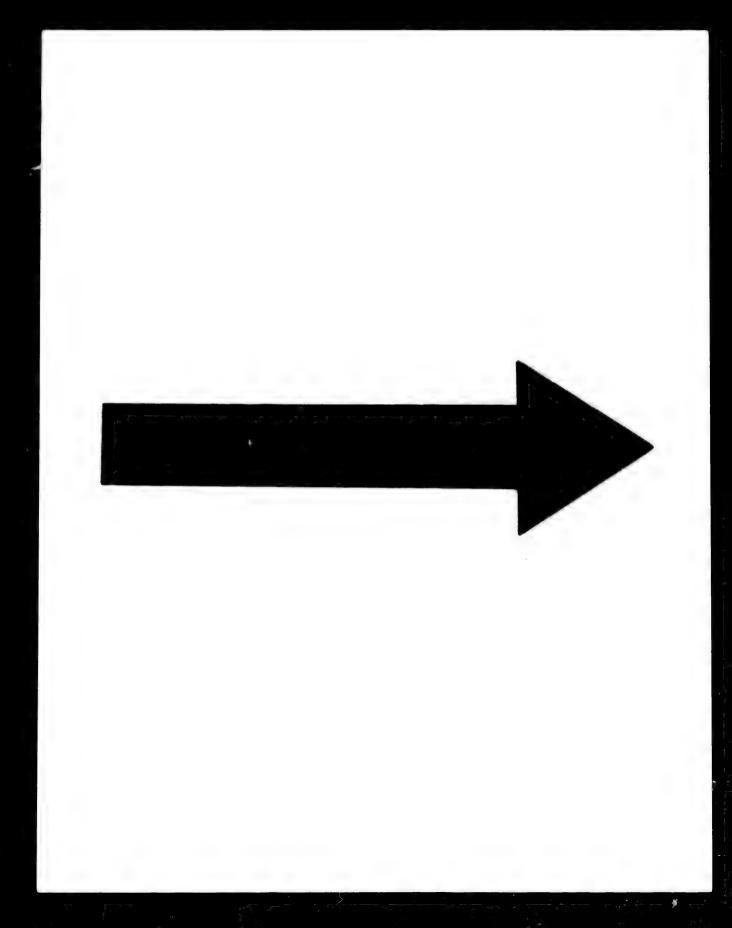

When in the fall plumage and collected into flocks, they spend most of the time floating and feeding with their peculiarly graceful dipping motion a few yards from the beach, while a flock will occasionally rise with a sharp twitter and move a few hundred yards to a new feeding ground.

They are exceedingly tame and unsuspicious at all seasons, and the Eskimo boys, although their archery is none of the best, succeed in killing a good many of them with their bows and arrows.

### 564. LOBIPES HYPERBOREUS (Linn.) Cuv.

NORTHERN PHALAROPE (Sabra'ñna).

Mr. Nelson has already noted the increasing rarity of this species as we proceed towards the north in the Arctic Ocean, although it is the more abundant of the two Phalaropes on the shores

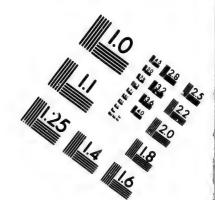

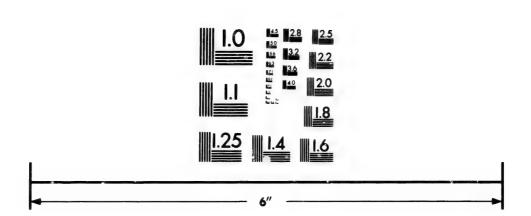

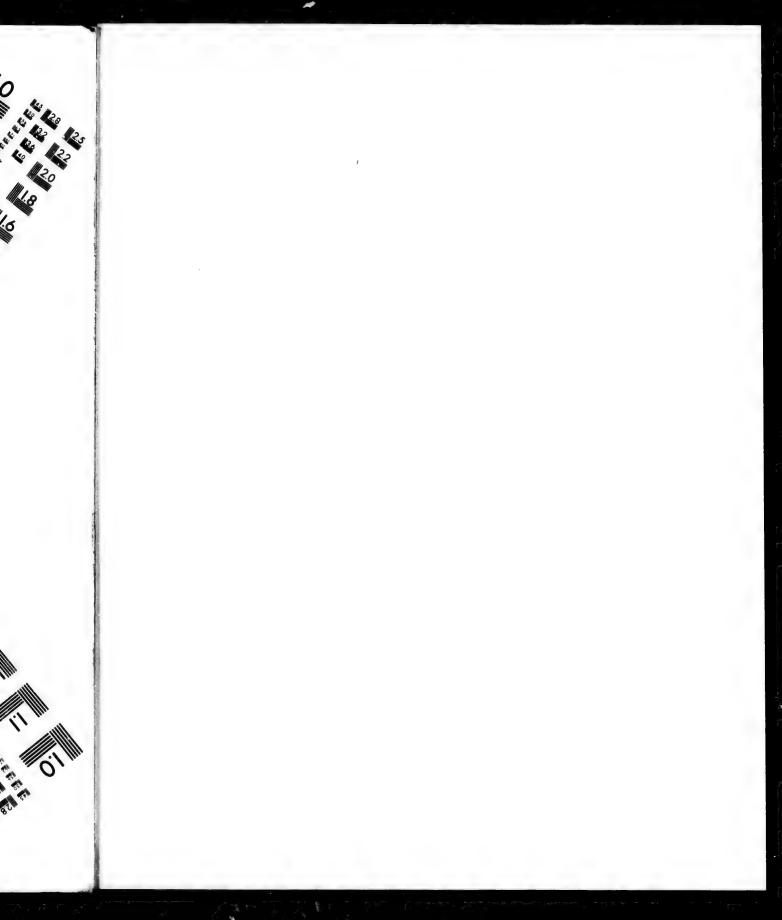

IMAGE EVALUATION TEST TARGET (MT-3)

Photographic Sciences Corporation

23 WEST MAIN STREET WEBSTER, N.Y. 14580 (716) 872-4503 STATE OF THE STATE

of Bering Sea. When we reach Point Barrow it has become merely a rare straggler, although the natives know it well, having become familiar with it during their summer wanderings to the Colville.

It was only seen alive on one occasion, June 11, 1883, when a single pair was taken in one of the small tundra pools, such as are frequented by the Red Phalaropes. As usual the female was the larger and more brightly colored bird.

We also secured a native skin from a man who said he had shot the bird in the country of the Kûngmûdling people, east of the Colville River, where they are very plenty.

## 584. GRUS CANADENSIS (Linn.) Temm.

LITTLE CRANE (Tût-tř'd-rř-qû).

Though abundant about Norton Sound and even as far north as Kotzebue Sound, the Little Crane reaches Point Barrow only as a rare straggler. It was not observed at all during the season of 1882, but two pairs were seen in 1883 and one of each pair secured. Both of these occurrences were between the middle and end of June, and none were seen in the autumn.

The bird was well known to the natives, who say they find them very abundant at the mouth of the Colville.

### 588. OLOR AMERICANUS (Sharpless) Bp.

Whistling Swan (Ku'a' ru).

The swans occasionally seen and frequently spoken of by the natives are probably of this species, as the large Trumpeter Swan is not known west of Fort Yukon (teste Nelson, "Arctic Cruise of the Revenue Steamer Corwin, 1881").

They were only noticed once or twice each spring, and the natives say they are uncommon at the sea-coast.

They say, however, that they are very plenty "pani" "south," by which they mean 75 or 100 miles inland on the rivers, where, they say, they catch a great many when they have molted their wing feathers.

## 591a. CHEN HYPERBOREUS ALBATUS (Cass.) Ridgw.

LESSER SNOW GOOSE (Kil'ñ o).

All the snow geese taken were of this smaller form. They are not at all common, but are occasionally seen during the spring migrations, that is, from the middle of May to the end of June. They are usually in pairs and small fleeks, and generally come off the land from the south and go out to sea, as if going out to feed.

Once or twice larger flocks came up in the morning and went back again in the afternoon, and occasionally stragglers were found alighting round the pools on the tundra. None of them bred in the neighborhood of the station.

### 593a. ANSER ALBIPRONS GAMBELI (Hartl.) Coues.

AMERICAN WHITE-FRONTED GOOSE (Nú'a' lúa' rua).

This was our most abundant goose. They are fairly plenty during the spring migrations and a few breed. Like the swans they are said to be extremely abundant "south," near Meade River, where many eggs are secured and many geese taken while molting and unable to fly.

They arrive about the middle to the end of May (May 16, 1882, and May 25, 1883), and for a couple of weeks are generally to be found in small parties along the lagoons and the small pools which rave opened along the crown of the beach. We could be sure to find a few geese every day in a small marshy lagoon above the station, which we got into the habit of calling the "goose pond" from this fact.

As the snow cleared off—early in June—they scattered in pairs over the tundra, occasionally feeding together in small parties of half a dozen or so.

The eggs are always laid in the black, muddy tundra, often on top of a slight knoli. The nest is lined with tundra moss and down. The number of eggs in a brood appears subject to considerable variation, as we found sets of four, six, and seven, all well advanced in incubation. The last laid egg is generally in the middle of the nest, and may be recognized by its white shell unless incubation is far advanced, the other eggs being stained and soiled by the birds coming on and off the nest.

We never saw any young birds, and the adults disappeared early in July. Perhaps they go inland to the rivers to molt their flight-feathers.

In the fall migrations they were exceedingly rare, a flock or two being seen each season in August.

These birds are familiar objects, during the breeding season stalking around the level tundra, where the mirage makes them loom up as big as a man, and their peculiar laughing cry is frequently to be heard.

At this time they are exceedingly shy and difficult of approach, but when they first arrive can easily be called within gunshot by the rudest imitation of their cry.

### 596. BERNICLA NIGRICANS (Lawr.) Cass.

## BLACK BRANT (Nûg'tû'g'nû).

The Black Brant appear at the end of the main spring migrations of the water-fowl, but in no very considerable numbers, following the same track as the eiders.

A few remain to breed and are to be seen flying about the tundra during June. The nest is placed in rather marshy ground and is a simple depression lined with down, with which the eggs are completely covered when the birds leave the nest. The birds sometimes begin to sit on four eggs and sometimes lay as many as six.

After the middle of August they begin to fly across the isthmus at Pergniak, coming west along the shore of Elson Bay, crossing to the ocean and turning southwest along the coast. Whenever during August the wind is favorable for a flight of eiders at Pergniak the brant appear also. They, however, frequently turn before reaching the beach at Pergniak, follow down the line of lagoons and cross to the sea lower down the coast.

The adults return first. No young of the year were taken till the end of August. During the first half of September, a good many flocks cross the land at the inlets as well as at Pergniak, and are to be seen resting and feeding along the lagoons and pond-holes.

At this season they are very shy and hard to approach, and all are gone by the end of September.

## 598. PHILACTE CANAGICA (Sevast.) Bannist.

## EMPEROR GOOSE.

This bird did not occur at Point Barrow, and its name is only inserted here because the expedition received the gift of a skin at Saint Michael's from Lieut. Frederick Schwatka, U. S. A.

## 605. DAFILA ACUTA (Linn.) Bonap.

### · PINTAIL (Îvicâgâ).

The Pintail does not come to the coast in anything but small numbers, and probably none breed in the vicinity of the station.

One or two small flocks were occasionally seen during the spring migrations in 1882, but none in 1883, until the fall.

During the fall migrations, that is through August and early in September, several small parties came down into the little ponds near the village and several were taken. These returning birds were mostly young of the year, and very fat.

The natives say that they are very plenty in summer on the larger rivers running into the Arctic Ocean east of Point Barrow, and are very keen of sight and hearing.

#### 623. HARELDA GLACIALIS (Linn.) Leach.

LONG-TAILED DUCK: OLD SQUAW (A'hadlin, A'dyigia).

This was one of our commonest ducks, though never appearing in great flights like the eiders. They are first seen about the middle or end of May, and remain as long as there is any open water in the fall. The seal hunters in 1882 reported seeing these birds as late as December 9, in open holes in the ice-field.

Though the first ones arrive from the 15th to the 20th of May, they are not plenty till the first week in June, about which time there is a considerable flight, larger flocks passing up to the northeast in the afternoon or evening.

The flight-flocks are never so large as the flocks of eiders, and always go very high, making a great clamor. They are exceedingly noisy all through the spring migrations and the breeding season. The native name "Ahadliñ" is a capital imitation of their ordinary cry.

After this flight they are to be found in tolerable abundance in all the ponds and pools on the tundra which are free from ice. They appear to have paired before their arrival, and only seldom collect in small parties at some favorite feeding ground like the "goose pond."

During the breeding season each pair seems to adopt a pool for its own, and drive out all intruders. At this season they feed almost exclusively on vegetable food, and are fat and in excellent condition for food, with no fishy tlavor.

They breed in considerable numbers all over the tundra, but the nests are scattered and not easy to find. The nest is always lined with down and generally near a pool.

As the open holes begin gradually to form at the outlets of the lagoons, and along the beach, the Old Squaws resort to them in increasing numbers, frequently sitting on the ice. By the first week in July they begin to abandon the tundra and collect in large flocks along the shore.

After the ice has broken up and gone away they are to be looked for especially along the shore, although a small party is generally to be found in each of the large lagoons. Through July and Angust they vary in abundance, some days being very plenty, while for two or three days at a time none at all are to be seen. At this season they fly up and down not far from the shore and light in the sea. Towards the end of August they are apt to form large "beds" near the station, and this habit continues in September whenever there is sufficient open water.

Many come from the east in September and cross the isthmus at Pergniak, and continue on down the coast to the southwest. We noticed them going southwest past Point Franklin, August 31, 1883, in very large flocks.

After October 1 they grow searcer, but some are always to be seen as late as there is any open water.

They begin to lay about the middle of June, and downy young were found July 20.

## 625. POLYSTICTA STELLERI (Pall.) Brandt.

STELLER'S DUCK (Ignikan'kto).

Though not common in the sense that the King-ducks and Pacific Eiders are common, this beautiful little duck is far from a-rare bird during the late spring and summer at Point Barrow and in the vicinity.

The breeding-ground, however, appears to be some distance off. Early in June they are to be found at the "leads" of open water at some distance from the shore, and perhaps the majority of them pass on in this way to their breeding-grounds. From the middle to the end of June they appear on land in small parties scattered over the fundra.

At this time they are in full breeding plumage, and the males are generally in excess in the flocks. They are generally to be found in small "pond-holes," frequently sitting on the bank asleep, and are very tame, easily approached within gunshot, and generally swimming together when alarmed, before taking wing, so that several can be secured at one discharge. I have stopped a whole flock of five with a single shot.

They appear to go off to breed about the end of June, although it is possible that the birds we have on the tundra are non-breeding birds.

Birds, however, that have bred, judging from the looks of the ovaries, begin to come back from the first to the middle of July, appearing especially at Pergniak and flying in small parties up and down the coast. They generally keep to themselves, but are sometimes found associating with small parties of King-ducks.

When the open water forms along shore, that is, in the latter part of July and early part of August, they are to be found in large flocks along the beach, collecting in "beds" at a safe distance from the shore, feeding on marine invertebrates, especially gephrycan worms. These flocks consist almost exclusively of molting females, whose ovaries show that they have bred. The males appear to undergo a fall change of plumage like the other eiders, gradually putting on the brown dress of the females. We were, however, unable to secure any specimens to illustrate this change.

They disappear from the first to the middle of August, and when gathered in large flocks are exceedingly wild and hard to approach.

Though less abundant in the early part of the season of 1883 than they had been in 1882, they were, on the other hand, much more plenty after the sea opened, and staid considerably later.

## 626. LAMPRONETTA FISCHERI Brandt.

Spectacled Eider (Ka'waso: & Tútúlu: & Yû'kalulu).

This species has not been previously noted north of Bering Straits, but we found it to be a regular though rather rare summer visitor in the vicinity of Point Barrow. They evidently breed not far from the station, as a female was taken June 19, 1883, with an egg in the oviduct just ready for laving.

They arrive towards the end of the great spring migrations of eiders, as has been observed at Saint Michael's, in company with the King-ducks and Pacific Eiders, and are occasionally to be seen in pairs and small parties on the tundra, especially on the wetter portions back of the beach lagoons.

They were not observed either season in the fall migrations. The young, about three-fourths grown, were taken August 24, 1883, and had the eye-patches even then distinctly indicated.

The male in the breeding season has the green feathers of the back of the head developed into a decided nuchal crest, which I do not find mentioned in any of the published descriptions of the species.

I found the iris of the female white, and not hazel or blue as has been stated by other observers. This character is possibly variable.

### 628. SOMATERIA V-NIGRA Gray.

PACIFIC EIDER ( & Amaw'lin; & Teu galù'ktun).

This species appears to be decidedly less plenty than the succeeding, although it is often difficult to distinguish them, as during the great migrations they frequently associate in large mixed flocks, so that one shot may bring down birds of both species.

They arrive later than the King Eiders, not appearing before the middle of May, after which time they are to be taken in every flight, gradually increasing in numbers. Towards the end of the migrations there are occasional days when the flocks seem to be made up almost exclusively of this species. A few small parties are also to be seen loitering around the lagoons, and open pools in the shore ice towards the end of June.

During the migrations, they are exceedingly fat and excellent eating. In the autumn they associate with the King Eiders, following the same course at Elson Bay, and frequently sitting in good-sized parties close to the shore.

Towards the end of the fall migr. tions, the change to the fall plumage in the males is pretty well marked. This change of plumage has been noted in this species by Mr. Dall, but beyond has short note, I can find no reference to the change in any history of the species. Unfortunately, no specimens were secured to illustrate this.

This species does not breed anywhere near the station. The natives say they all go a long distance to the eastward, and there breed in large numbers. As well as we could make out, one extensive breeding-ground is on some sand island, rather more than half-way between Point Barrow and the mouth of the Colville River.

By a curious misnomer, these ducks are known to the whalemen as "canvas-backs"!

## 629. SOMATERIA SPECTABILIS (Linn.) Boie.

King Eider ( & Ki'nalin; 9 Annabia).

This is by all means the most abundant bird at Point Barrow. Thousands hardly describes the multitudes which passed up during the great migrations, within sight of the station, and yet equally great numbers passed up along the "lead" of open water several miles off shore.

They appear in the spring before there is any open water except the shifting "leads" at a distance from the shore, and travel steadily and swiftly past Cape Smythe to the northeast, following the coast. Some flocks cross to the eastward below Point Barrow, but the majority follow the barrier of grounded ice past the point. It is probable, however, that they turn to the east after passing Point Barrow, because all the returning flocks in the autumn come from the east, hugging the shore of the mainland.

The first ducks in the spring of 1882 were seen on April 27, a comparatively warm day, with a light southerly wind blowing. They were flying parallel to the coast over the barrier of grounded ice. The natives said they were all "kingaling" "nosy birds" or males (referring to the protuberance at the base of the bill), and the first flocks of the migration appear to be composed exclusively of males.

During the first half of May, 1882, several males came from the south off the land, and gained the ice in a very exhausted condition, frequently so utterly worn out that the natives caught them and killed them with sticks. They were all found to be very much emaciated, and their stomachs were empty of food.

The season was later in 1883, and no ducks were seen till May 5. There were six great flights in 1882, the first on May 12 and the last on June 11, and five in 1883, the first on May 17 and the last on June 4. As a rule, these flights took place on comparatively warm days, with light westerly or southwesterly winds. On one day each year, however, there was a large flight with a light breeze from the east. A warm southwest wind is pretty sure to bring a large flight of eiders.

The flight seldom lasts more than two or three hours, beginning about eight or nine in the morning, or between three and four in the afternoon. More rarely a flight begins about ten in the morning and lasts till afternoon.

During the flights, the great flocks in quick succession appear to strike the coast a few miles from the station, probably coming straight across from the Seahorse Islands, and then follow up the belt of level ice parallel to the coast towards Point Barrow, going pretty steadily on their course, but swerving a little and rising rather high when alarmed.

Their order of flight was generally in long diagonal lines, occasionally huddling together so that several could be killed at one discharge. A few flocks in a great flight usually followed up the line — broken ice a mile or two from the shore, and a flock occasionally turned in at the mouth of the lagoon and proceeded up over the land.

On the days between the flights and when the wind was east, a few flocks would struggle up against the wind either going up far off the shore or overland; but most of the birds on "off days" came off the land from the south, and either continued on towards the open water or turned to the northeast along the broken ice. These flocks were never so large as the great flight flocks, and generally flew in more compact order. A few were occasionally seen early in the migrations going back towards the southwest. On many days when there were no ducks in shore they flew abundantly at the "lead" of open water.

The majority of them are paired by the middle of May, and the flocks are made up of pairs flying alternately, ducks and drakes. If a duck is shot down, the drake almost invariably follows her to the ice, apparently supposing that she has alighted.

Early in June straggling pairs and small parties settle about the tundra pools and breed sparingly in the neighborhood of the station. A few nests were found. After the main flight and during the latter part of June a few stragglers and small flocks are to be seen almost daily.

Captain Owen, of the steam whaler North Star, who got up to the station June 25, 1882, reported that the day before there were myriads of eiders of both sexes in the open water off Point Belcher.

By the second week in July, before the ice is gone from the sea or from Elson Bay, the males begin to come back in flocks from the east, and from that time to the middle of September there is a flight of eiders whenever the wind blows from the east. The flocks are all males at first, but mixed flocks gradually appear, and the young of the year were first observed in these flocks on August 30, 1882.

Most of the flight birds make no stay but continue on to the southwest, generally a couple of miles out at sea, though they occasionally stop to rest, especially when there is much drifting ice. Between the regular flights they continue to straggle along, coming off the land, and occasionally siting apparently asleep on the beach. Small flocks and single birds are to be seen till the sea closes, about the end of October, and in 1882 many were seen as late as December 2, when there were many holes of open water.

When the birds are flying at Pergniak, it is quite a lively scene, as there is a large summer camp of Eskimos close to the point where the ducks cross when the conditions are favorable. When the wind is east or northeast, and not blowing too hard, the birds come from the east and strike the land at a point which runs out on the shore of the bay about half a mile from Pergniak, close to where the lagoons begin.

They would be apt to turn and fly down these lagoons were it not for a row of stakes, set up by the natives, running round the semicircle of the bay to the camp. As soon as the flock reaches this critical point, all the natives, and there may be fifty of them on the watch with guns and slings, just at the narrowest part of the beach above the tents, immediately set up a shrill yell. Nine times out of ten the flock will waver, turn, follow round the row of stakes, and naturally whirl out to sea at the first open place, where of course the gunners are stationed. With a strong wind, however, the ducks do not follow the land, but come straight on from the east and cross wherever they happen to strike the beach, so that the shooting cannot be depended on.

The flocks during the fall flight are not so large and do not follow one another in such rapid succession as in the spring, and though they arrive from the east in the same stringing order, they huddle into a compact body as they whirl along the line of stakes and out over the beach.

The natives, although as a rule they are far from good shots, are provided with poor guns, and appear particularly averse to putting in enough powder and shot to kill a strong eider duck, nevertheless succeed in capturing a good many with guns and slings. They reap a plentiful harvest of them in the spring, when they are all at home, and the crews of the whaling umiaks out at the open water spend their leisure time while they are waiting for whales in shooting ducks, which form an important article of food. They of course always boil their ducks, as they do all the rest of their food, and usually skin instead of plucking them. They are very fond of the fat which adheres to the skin, scraping it off with their knives industriously till not a particle remains, licking their knives with great relish. The intestines, boiled by themselves, are also considered a great delicacy.

The males that appear at Pergniak at the beginning of the autumn migrations are at first in full breeding dress, perhaps a little faded, especially about the bill. As the season advances they show more and more extensive patches of brown feathers, until at the end of the migrations they cannot be distinguished from the females except by the white wing and back patches.

I do not find this autumnal change of plumage me..tioned in any published account of the species, and it has been questioned on general principles by experienced ornithologists. I accordingly give a detailed description of three specimens brought home by our party, which illustrates this process very well. They were all taken on July 26, 1883, and exhibit three different stages of the change

1. Museum No. 93,296. Compared with a drake in full breeding dress, all the colors are more dingy. The black of the back has lost its rich velvety gloss, and the remiges and tail-feathers are

H. Ex. 44---16

faded and worn. The cream color of the throat and shoulders is much paler, fading almost to white on the back, and beginning to become mottled with darker patches between the shoulders. The white feathers on the neck are thin and sparse, and drop out very easily, while very young brown feathers are making their appearance among them. The black V on the throat has assumed a "spotty" appearance, caused by the dropping out of some of the black-tipped feathers, so as to expose their white roots. The green feathers of the cheeks are faded, thin, and hairy. The bluegray of the crown and back of the head appears at first sight to be merely faded, but drawing aside the feathers discloses at their roots a crop of brown feathers rather more advanced than those on the neck. All the feathers of the head and neck except the brown ones fall out very easily and appear faded and worn. The bill has grown dark, the protuberance at its base much shrunken, and the epidermis is coming off the frontal processes, patches only remaining.

2. Museum No. 93,297. The head and neck now show about equal proportions of the new brown feathers and the old light-colored ones. The back between the shoulders and the front part of the throat shows a large proportion of new brown feathers (still growing from the capsule, as may be easily seen by pulling out one or two), and many of the white or cream-colored feathers of the throat have been lost. A few new brown feathers have also appeared at the flanks.

3. Museum No. 93,298. The white and light-colored feathers are nearly gone from the head and neck, remaining only in a few patches on the cheeks and forehead, while the brown feathers are fairly well developed, so that the fore part of the throat and back is nearly as in the female. The breast is still cream-colored.

The drakes grow almost entirely dark before the migrations are over, the wing-patches remaining white the longest. The Pacific eider and Steller's duck both undergo a similar change, but we were mable to secure any specimens to illustrate this.

None of the eiders of any species molt their wing-feathers so as to be incapable of flight until after leaving the neighborhood of Point Barrow.

### 657, PAGOPHILA EBURNEA (Phipps) Kaup.

IVORY GULL (Nau'yabwûñ).

The Ivory Gull is at best a rare visitor at Point Barrow. Early in the spring of 1882, Lieutenant Ray reported seeing two in full plumage out at the lead of open water, some six miles from the shore.

No others, however, were seen or reported until late in the fall, when large numbers of Rosy Gulls were flying up the coast and among them a few of this species, of which one was taken.

The bird was not observed in the season of 1883.

## 660. LARUS GLAUCUS Briinn.

GLAUCOUS GULL; BURGOMASTER (Nauya).

Large gulls, mostly in the immature plumage of this species, were plenty round the station from the time we landed up to the middle of October, flying up and down the beach, sitting on the water, or feeding at the edge of the beach. The first two of the large lagoons were always favorite resorts for the gulls at all seasons when they were open, and even after they were partially frozen gulls were to be seen sitting on the ice.

After the middle of October, they became scarcer, sometimes disappearing for days, but a few stragglers remained as long as the sea was open, up to the middle of November. In the autumn of 1882 none were seen after October 18, except one solitary straggler reported November 1.

They arrive in the spring, about the first week in May, and during May and June a few are to be seen nearly every day, though they sometimes disappear altogether for a day or two, and occasionally are rather numerous specially round the lagoons and near Pergniak. They always turn out in full force when there is a flight of eiders, and make themselves troublesome by picking up dead and wounded ducks.

If a duck be shot so that he fall in the water or any not easily accessible place, an hour is generally time enough for him to be reduced to a skeleton by the gulls. They are occasionally to be seen inland, but usually crossing to some particular point, sometimes lighting on the tundra,

None breed anywhere near the station, though they are to be seen every day during the breeding season.

They are rather abundant after the sea opens, and continue so during August and September. The young appear in August. Towards the end of September, when numerous, they have a regular track near the station, flying in over the beach and out over the magnetic observatory.

The natives say they find them plenty at the rivers inland when they are killing deer in the summer.

They are a favorite bird with the natives, and many are shot in the autumn as they fly up and down the shore. They are also occasionally caught with a baited line in the autumn when there is a light snow on the beach. A little stick of hard-wood, about 4 inches long and sharpened at both ends, has attached to its middle a strong line of deer sinew. The stick is carefully wrapped in blubber or meat and exposed on the beach, while the short line is securely fastened to a stake driven into the sand and carefully concealed in the snow. The gull picks up the tempting morsel and swallows it and of course is caught by the stick, which turns sidewise across his gullet, and his struggles to escape fix it more firmly.

It was at first supposed that *Larus leneopterus* occurred at Point Barrow, and several gulls in the collection were identified as belonging to this species. Mr. Howard Saunders, however, the great English authority on the *Laridw*, while in Washington last summer, carefully examined our series, and is of the opinion that they are all referable to *L. glancus*, with the exception of one small and very brown immature bird, which he was unable to identify.

## 661a. LARUS KUMLIENI Brewster.

LESSER GLAUCOUS-WINGED GULL (Nati-ya).

The above-mentioned dark and small immature bird (Museum No. 93306), which Mr. Saunders was unable to identify, is considered by Mr. Ridgway as probably referable to Brewster's species L. kumlieni,\* which has hitherto been obtained only from the eastern coast of America. It is not at all unlikely that the species should straggle westward along the northern coast of the continent as Pelidna subaranata and Actodromas fuscicollis were found to do.

Small and dark young gulls were observed quite often with the young Burgomasters in the antumn, but the above was the only one obtained in a state fit for preservation.

## 676. RHODOSTETHIA ROSEA (MacGill) Bruch.

Ross's Gull (Kā'āmax'lu).

(Plates I and II.)

Our expedition succeeded in obtaining a large series of this rare and beautiful bird—more, in fact, than there were before in all the museums of the world put together—and a still larger series might have been obtained had the weather and other conditions been favorable.

Unfortunately, we were able to add very little to the biography of the species, as the birds are simply autumn visitors at Point Barrow, making no stry, but passing rapidly to the northeast. This, however, is the only locality where the birds have been observed in abundance even for a short time, all previous records referring to the capture of sporadic individuals.

In 1881, from September 28 to October 22, there were days when they were exceedingly abundant in small flocks—generally moving towards the northeast—either flying over the sea or making short excursions inshore.

Not a single one was seen during the spring migrations or in the summer, but two or three stragglers were noticed early in September—a few out among the loose pack-ice—and on September 21, 1882, they were again abundant, apparently almost all young birds.

<sup>\*</sup> See Bull. Nuttall Ornithological Club, viii, No. 4, pp. 214-219, October, 1883.

They appeared in large, loose flocks, coming in from the sea and from the southwest, all apparently traveling to the northeast. Most of the flocks whirled in at the mouth of our lagoon and circled round the station with a peculiarly graceful, wavering flight, and many were shot close to the house. A cold easterly wind was blowing at the time.

They continued plenty for several days—while the east wind blew—all following the same track, moving up the shore, and making short excursions inland at each of the beach lagoous.

After September 28 they disappeared until October 6, when for several days there was a large flight. On October 9, in particular, there was a continuous stream of them all day long moving up the shore a short distance from the beach and occasionally swinging in over the land. Note there seen to return.

The nature of our duties at the station prevented any investigation as to where they came from or whither they went. They appeared to come in from the sea, to the west or northwest, and

traveled along the coast to the northeast.

They were not observed on Wrangel Island by either the Jeannette, the Corwin, or the Rodgers, and yet the direction from which they come to Point Barrow in the fall points to a breeding-ground somewhere in that part of the world. May it not be that some land yet to be discovered, and north of Wrangel Island, will one day yield a glorious harvest of the eggs of this splendid species?

It is difficult to form any idea of what becomes of the thousands that pass Point Barrow to the northeast in the autumn. It is certain that they do not return along the shore as they went. Nevertheless, at that season of the year they must of necessity soon seek lower latitudes.

Perhaps the most plausible supposition is that soon after leaving Point Barrow, perhaps when they first encounter the main ice-pack, they turn and retrace their steps so far out at sea as to be unnoticed from the land, and pass the winter at the edge of the ice-field, proceeding north to their breeding-ground as the pack travels north in the spring.

Capt. Everett Smith, of the steam whaler Bowhead, who is a trustworthy witness, reports that when he was in the loose ice, 70 miles northwest of Point Hope, on June 10, 1883, he saw large

numbers of these birds.

The greater number of the birds we obtained were immature, and probably the young of the year, though in a stage slightly more advanced than the young bird taken by Mr. Nelson at St. Michael's. The few adults that we captured were in a plumage hitherto undescribed, and one in particular was especially beautiful. The following is a description of this specimen:

Museum No. 93321, Rhodostethia rosea & .—White parts everywhere tinged with rose color, except the tail feathers; rose color somewhat blotchy and approaching salmon color, especially on the crissum. Mantle pearly blue, extending as mottled markings to the back of the head. No traces of the black collar; a few black marks round the eye. Edge of wing from shoulder to wrist bright rose. First four primaries rose-shafted beneath, third the brightest; outer web of first primary black nearly to the tip; fifth to last primary and first secondary, white-tipped; remaining secondaries rose-tipped. A few small obscure black markings on the breast. Feet, "terra-cotta" red, with brown knuckles and webs. Bill, black.

The above description was taken from the freshly-killed bird. The beautiful blush-rose tinge had not, however, faded perceptibly, when the skin was examined a year later. The other adults were in almost the same plumage, but the rose color was much paler and confined to the under parts from the throat to the under tail-coverts. The only adult female secured was the least pink of any of the adults. One specimen, No. 93364, shows a few dark feathers among the upper wing-coverts. Mr. Ridgway makes the rather reasonable suggestion that this is a bird in its second year.

Mr. Howard Saunders, in "Ibis" for 1875, has given an excellent description of the immature plumage from two young birds in the Vienna Museum. As, however, these birds differ in some respects from those we collected, I will venture to give a detailed description of our large series.

Three specimens (Museum Nos. 93328  $\delta$ , 93353  $\delta$ , and 93354  $\delta$ ) present a stage of plumage which is possibly a little younger than the great majority of the birds collected.

The following is a description of this stage:

Below, including lower tail-coverts, white, or slightly tinged with rose-color; mantle pale nearly blue, extending on to the sides of the neck and back of the head, which is faintly mottled with dark markings in one specimen; black and white mottled markings round the eye, extending to the corner of the mouth in one specimen; small black spot on each side of the neck, while in one case the dark collar of the adult is faintly indicated; forehead in every case white; rump more or less mottled with black feathers, occasionally edged with white or pale brown. Upper tail-coverts white, sometimes showing indistinct dark marks towards the tips of the feathers. Tail with a broad black tip about one-fourth of its length. Middle rectrices black-shafted, with this color extending more or less on the webs, continuous with the black of the tip. First, second, third, and fourth primary above, shaft, outer web, and about half of inner web including tip, black, the rest white; one specimen has a large white subapical spot on the fourth primary. Remaining primaries gray at the base, fading into white towards the tip, where there is an oblique black bar across the feather. This bar grows smaller on the successive primaries till the last is wholly white. Secondaries, white. Tertiaries and scapulars dusky black, with white or light-brown edges. Upper wing-coverts, alula, and lower primary coverts black, with white or light brown edges, lower secondary coverts like the mantle. Under surface of the wing nearly uniform, like the mantle.

The majority of those taken were in a very similar plumage, but always without the black shafts to the middle rectrices, though the tail is always black-tipped, and one or two show slight black markings on the upper tail-coverts. In two or three specimens the blue of the mantle extends completely around the neek, and two or three have the dark collar faintly indicated, especially on the back of the neck. Two have a few scattered dark feathers in the blue of the mantle, and two have a few on the sides of the neck where the black spots are invariably present. A few specimens have the upper wing coverts indicating a change to the adult plumage. One has a few "mantle-blue" feathers mixed with the mottled ones, and three or four others have about the upper half of the coverts like the mantle. The white markings on the first four primaries are rather variable. One specimen has a small subapical spot on the outer web of the second, a large one on the third, and about half the outer web of the fourth, white. The fourth primary is frequently in this condition when the others are unspotted, and the spot appears occasionally on the third.

The outer web of the first appears always to be black.

About a third of the birds examined in this stage were more or less tinged with pink, and four-fifths of these were males, so that this may be more or less of a sexual character.

Both the specimens examined by Mr. Saunders lack the black tip to the tail so characteristic to this stage of plumage in the autumn. The date of capture of his specimens is unknown, but it is quite possible that they are the young of the previous year after the spring molt.

## 677. XEMA SABINEI (J. Sabine) Leach.

## Sabine's Gull (Yûkû'drigûgia).

Though by no means uncommon, this bird is somewhat irregular in its occurrence at Point Barrow. In 1881 the young birds of the year, easily recognized by the broad, black band from the shoulder to the tip of the wing, were quite abundant from the time we landed till the end of October.

In 1882, however, none were seen after August 3, and they were scarce during the breeding season. On the other hand, though equally scarce in the breeding season of 1883, they appeared in considerable numbers late in July and during the month of August, and were frequently seen in considerable flocks, young and adults together, about the lagoons, and with the other gulls collected round the whale-ships anchored at the Point.

They evidently breed somewhere in the neighborhood, probably on the sandy islands east of Point Barrow, for one was taken June 28, 1882, with the breast bare of feathers, as if incubating, but the eggs were never found.

They are usually to be seen flying singly up and down the shore with a peculiarly slow, wavering flight, zigzagging to right and left, and occasionally light upon the water close to the beach. Early in the season they are occasionally found flying some distance inland, and lighting among the tundra pools.

The first stragglers appear in the spring, about the first of June. An adult male, in full breeding plumage, taken in June, 1882, had the under parts as rosy as'in the Roseate Tern.

#### 687. STERNA MACRURA Naum.

ARCTIC TERN (Utyutákin).

The Terns appear about the 10th of June, but are never plenty about the station till the month of Angust, when they appear in good-sized flocks, fishing about the lagoons and among the broken ice, especially in the neighborhood of the sandspit at Point Barrow.

During the breeding season we only saw stragglers from the breeding grounds, which are probably the same as those of Sabine's gull, the sandy islands east of Point Barrow. None of our party succeeded in finding the nest, as we were unable to reach these islands, but eggs were brought as by the natives, who said they got them there.

The Terns leave early. None were seen after the end of August.

## 697. STERCORARIUS POMATORHINUS (Temm.) Vieill.

POMARINE JAEGER (T'suñû).

This is perhaps the least common of the three species of Skuas, although a regular summer visitor. They are to be seen flying about the tundra and occasionally lighting during the months of June, July, and August.

None of them breed anywhere near the station. The natives make no distinction between this and the two following species.

11

Th

the

as

## 693. STERCORARIUS CREPIDATUS (Banks) Vieill.

RICHARDSON'S JAEGER (I'sunu).

This appears to be rather more plentiful than the last species, but is nowhere to be compared in abundance to the following. They are occasionally to be seen during the summer, both before and after the sea opens, flying about with the other Skuas.

None breed anywhere near the station, and from the looks of the sexual organs of some taken early in July, they are late breeders.

## 699. STERCORARIUS PARASITICUS (Linn.) Saunders.

LONG-TAILED JAEGER (I'sunû).

This is by all means the commonest of the Skuas at Point Barrow and is rather abundant, though none breed. They arrive in the spring, about the end of May, and are tolerably plenty from that time till the end of August.

Before the sea opens they are to be found on the tundra, where they have a habit of walking about in small parties, feeding on flies. At such times they are not at all shy, and if one be shot down the others are apt to fly back within gunshot, sometimes coming straight at the shooter.

They are sometimes to be seen traveling about in large, straggling parties, fifty or more together, moving slowly up or down the coast, occasionally alighting and then taking wing again.

The natives say they are "bad" and eat birds' eggs, and they point out the broken egg-shells which are to be found scattered over the tundra as the work of this bird. We never happened to see them eating any eggs, but they certainly act as if they were searching for nests, and they have been seen in suspiciously close proximity to ducks' nests which were found broken up.

Their bad reputation is probably well deserved, as the natives of the Norton Sound region are said to tell the same story.

After the sea opens they are rather less abundant, but are still seen occasionally both on land and at sea.

### 737. COLYMBUS ADAMSI Gray.

GREAT WHITE-BILLED LOON (Tu'd'liñ).

The Great Loon, which is curiously enough called by the same Eskimo name as the Golden Ployer, is a regular summer visitor and probably breeds, though the eggs were never found.

They were not often noticed in the season of 1882, but were quite abundant in 1883. They are first to be seen about the end of May, or early in June, at the "lead" of open water and flying inland to their breeding grounds. As the sea opens along the shore and open holes are found in the lagoons they are to be looked for in such places, gradually going out to sea as the season advances.

They are generally to be seen alone or in pairs, seldom more than three or four together, and are silent birds compared with *C. torquatus*. I only heard this bird "laugh" once during the whole of my stay. The "laugh" appeared to be harsher than that of *torquatus*.

Fully fledged young were seen August 7, 1883. The breeding-grounds are probably around the swamps and lakes some distance inland.

C. torquatus, although reported by Mr. Nelson from the shores of the Arctie, was not observed at Point Barrow during our stay there.

## 739. COLYMBUS PACIFICUS Lawr.

PACIFIC DIVER (Kà'ksau).

All the black-throated loops we obtained proved upon examination to be this species, so that this is probably the only one that occurs.

The natives make no distinction between this and the next species, and they are both very common birds. Their peculiar harsh cry, "kok, kok, kok," from which they get their name, "Kāksau," is to be heard all summer, and the birds were seen nearly every day, flying backwards and forwards and inland from the sea.

During the breeding season these smaller loons have a habit of getting off alone in some small pond and howling like a fiend for upwards of half an hour at a time. It is a most blood-cardling, weird, and uncanny sort of a scream, and the amount of noise they make is something wonderful. They can be heard for miles.

They arrive early in June, and before the pends are open are generally flying eastward as if they had come up along the open water at sea and were striking across to the mouths of the rivers at the east. As the pends open they make themselves at home there, and evidently breed in abundance, though we were unable to find the nest. One of their breeding grounds was evidently a swampy lagoon some five or six miles inland, but the nests were inaccessible.

After the breeding season they are frequently to be seen in the open pools along the shore, especially when the lagoons have broken out. They are always very wild and difficult to secure. They are plenty through August and the greater part of September along the shore, and occasional stragglers remain round open holes well into October. Some appeared to be feeding young as late as the middle of September, 1882, as they were seen going inland from the sea carrying small fish.

#### 740. COLYMBUS SEPTENTRIONALIS Linn.

RED-THROATED DIVER (Kā'ksau).

This species is quite as common as the foregoing, and appears to have precisely the same habits.

The only identified loons' eggs we obtained were of this species, and were brought in with the parent bird from a stream some miles east of the point. The natives also brought in from time to time both seasons a number of eggs of the Kaksau, and these all appeared to be this species.

## 560. URIA GRYLLE (Linn.) Brünn.

BLACK GUILLEMOT (Sú'kûbirû).

During the season of open water we only saw one or two of these birds, always in full black plumage, and at some distance from the shore. In November and December, however, in fact as long as there are any pools and "leads" of open water, these birds in winter plumage are to be found in considerable numbers, usually in small flocks. They only leave us when the ice becomes solidly packed by the winter gales, and curiously enough are not to be found during the spring migrations. A number were taken in the winter of 1882, and with one exception were all the young of the year.

## 764. LOMVIA ARRA (Pall.) Bp.

THICK-BILLED GUILLEMOT (A'tpa).

This species, the "Crowbill" of the whalemen, reaches Point Barrow only as a rather rare straggler. They were sometimes seen at the lead of open water in the early spring and during the summer at some distance from the shore. One was taken as late as December 9, 1882, out among the broken ice by one of the seal hunters. We found them quite plenty at the Seahorse Islands on our return yoyage, and of course extremely abundant about Cape Lisburne.

# III.-FISHES.

By John Murdoch, A. M., Sergeant Signal Corps, United States Army,

Fishes were scarce in the neighborhood of the station, and the shortness of the open season rendered collecting exceedingly difficult. The marine species were almost all obtained from the natives, who caught them while fishing for food through the ice.

The fresh-water ponds and small streams around Point Barrow are quite barren of fish life, and the fresh-water species in the collection come from the great rivers east of Point Barrow, whence they were brought in frozen in the fall and early spring.

Dr. Tarleton II. Bean has kindly identified the species of the difficult genera Gymnelis, Lycodes, Lingis, and Cottus, and has verified the writer's identification of the other species.

### GASTEROSTEIDÆ.

### 1 GASTEROSTEUS PUNGITIUS L. subsp. BRACHYPODA Bean.

On December 1, 1882, Capt. E. P. Herendeen brought in a number of large burbot (*Lota*) from Meade River and Kuaru, both streams flowing into the Arctic Ocean east of Point Barrow.

On preparing these for the table, one or two were found to have their stomachs literally crammed full of sticklebacks, which or examination proved to belong to this species.

They were most of them fresh enough for preservation.

### GADIDÆ.

## 2. BOREOGADUS SAIDA (Lepech.) Bean,

This species was found to be quite plenty close to the station at most seasons of the year. We first saw them early in October, 1881, when the natives brought down large numbers from Point Barrow, where they had been washed up on the beach.

Usually during the latter part of October and early in November, after the sea has closed, and when tide-cracks form along the shore, the natives generally catch a good many of them at the very edge of the beach in about a foot of water.

They use a short line of whalebone to which is attached a small lure made of blackened ivory, which roughly represents an amphipod crustacean, and is armed with a barbless hook.

After this, no more are caught till after the return of the sun, early in February. The natives say that they go away, and it is quite probable that they leave the shore and go off into deeper water. If there were any fish to be caught, the natives would undoubtedly fish for them during the winter months, as at this season they are frequently hard pressed for food.

Early in February, they become exceedingly abundant in about 15 fathoms of water, wherever there is a level field of the season's ice not over 4 feet in thickness, inclosed between rows of hummocks of broken ice. Such a field as this was formed in the winter of 1882, and remained unchanged from February till about the middle of May, when the ice began to soften and melt on the surface. Large numbers of the natives from the Cape Smythe village, especially women and children, resorted

129

H. Ex. 44---17

rare g the nong lands

dack et as ound didly igra-

ng of

to this field nearly every day and caught these fish literally by the bushel. The method of winter fishing is as follows: A hole about 18 inches square is cut through the ice, and through this is let down a long line made of strips of whalebone, and provided with a sinker of lead or copper and two small pear-shaped "jigs" of bright copper or walrus-ivory, armed with four barbless copper hooks. The reel on which the line was wound and which is a stick about 18 inches long serves as a rod, being held in one hand, while a long-handled scoop is held in the other hand and is used to keep the hole clear of ice. The jigs are kept close to the bottom and the line is continually jerked up a short distance and allowed to sink again. The fish are attracted by the bright "jig," and "nosing" round it are caught by the upward jerk. The line is recled up on the two sticks, held one in each hand, so that it never has to be touched with the fingers, and the fish is adroitly jerked off the hook on to the ice.

No such field, or "fishing ground," as we were in the habit of calling it, was formed in 1883, and only comparatively few fish were eaught.

Early in July, when open holes of water form along the shore at the outlets of the lagoons, the fish are again to be found in considerable abundance. The young fry were first noticed about the middle of July, and were quite plenty in the shallow water at the edge of the beach.

Young fish, two to three inches long, were taken at the head of our lagoon, which is brackish, about the first of September, and at about the same time the full-grown fish were plenty along the beach in about 3 fathoms of water, swimming about in large, loose schools.

## 3. TILESIA GRACILIS (Tiles.) Swainson.

We found this species abundant along the shore at St. Michael's, and caught a good many with hook and line.

### 4. LOTA MACULOSA (Le S.) Rich

(Titálě.)

This species was abundant in Meade River and Kuaru. The natives catch many large ones through the ice with hook and line.

They are exceedingly voracious, and Captain Herendeen caught one in his net which had swallowed a white fish already caught in the net and then managed to entangle himself.

The season for catching them is in October and November, and again in February, March, and April. They are generally considered rather a refuse fish, and worthless for food, but we found that they made a very palatable chowder.

### LYCODIDÆ.

### 5. GYMNELIS VIRIDIS (Fabr.) Reinhardt.

A small specimen was found washed up on the beach September 13, 1882. Its colors when fresh were two shades of orange, with the spot at the beginning of the dorsal fin black, edged with white.

## G. LYCODES TURNERII Bean.

(Kúxraunä.)

Two specimens were obtained, having been caught by the natives while "jigging" Polar cod through the ice.

The following color-notes were made while the fish were fresh. Collector's No. (metal tag) 6; Museum No. 33,922 ?: Ground-color a rather light-reddish chocolate, shading into a reddish brown on the belly. Head, underneath, white. Lower edges of pectorals and ventrals, rufous red. Interrupted band from eye to edge of operculum, brownish cream-color edged with chocolate. Crescent-shaped band on top of head, same color. Ten lateral bands of the same color with dark edges, broken on the side of the body and appearing as spots. Indistinct tip to caudal. Creamy spot on pectoral, near root.

Collector's No. 26, Museum No. 33924 8; Large. Marked on the same general pattern as the female, but with only seven lateral bands. All the markings smaller and obscured. General color a brighter red, approaching scarlet.

#### 7. LYCODES COCCINEUS Bean.

This species was obtained with the preceding, and one large specimen was washed up on the beach. A small specimen had the following colors when fresh:

Collector's No. 7, Museum No. 33,923 & juv., 11.5 inches long. Paler than *L. turrerii*, with the contrast between the chocolate and cream color more strongly marked. Belly lighter, and the red more of a pale orange. Cheeks brownish orange. The second, fourth, and sixth bands end as roundish spots on the back; the alternate bands are continued down, widen, and nearly meet each other. Broad band on anal extending from origin about one-third the length of the fin.

## LIPARIDIDÆ.

#### 8. LIPARIS GIBBUS Bean.

On March 30, 1883, a small specimen much mutilated washed up in the tide-hole, covered with small amphipods (*Onivimus littoralis*). Radial formula: D. 43; A. 37; C. 12; P. 38. Museum No. 33,949.

### COTTIDÆ.

### 9. COTTUS DECASTRENSIS Knerr.

(Kû'n-ai-ó; kû'l-ai-ó).

These were obtained wherever Boreogadus saida was taken, but always in comparatively small numbers.

### 10. COTTUS QUADRICORNIS Linn.

This species was taken with the preceding, and the young were plenty in our lagoon, close to the outlet, in September, and also in the shoal water of Elson Bay, at Pergniak. Captain Herendeen brought in a small specimen of this species taken in a tributary of Meade River, some 80 or 90 miles from the sea. Its colors when fresh were: Ventrals, lower edge of pectorals, branchiostegal membrane, and edge of mouth, bright vermilion. Back, dark olive, shading through dark slate to white on the belly.

### MICROSTOMIDÆ.

## 11. OSMERUS DENTEX Steindachner

(Ithoánin).

In February, 1883, a Kungmeun Eskimo brought in a large number of these smelts, which he said were caught with hook and line in "The River" ("Ku"), supposed to run into Wainwright's Inlet. The species was well known to the natives at Point Barrow, who said that it occurred nowhere in the immediate neighborhood, and was always taken with hook and line.

### 12. MALLOTUS VILLOSUS (Müller) Cuv.

In 1882, after the sea was fairly opened, that is, about the 20th of July, these fish appeared along the beach in small numbers at first. A few days later they were passing up the shore close to the beach in very large schools, all moving northeast, and occasionally running into the mouths of the lagoons.

By July 25 they had all passed, and one female only was observed in the autumn. She was seined with a number of Polar Cod on September 5 close to the beach. None at all were noticed in the summer of 1883.

## COREGONIDÆ.

#### 13. COREGONUS LAURETTÆ Bean

This species appears to be abundant in the large rivers (Meade River and Kuaru) flowing into the Arctic Ocean east of Point Barrow, as large numbers were brought in frozen by the Eskimo deer-hunters, generally badly mutilated and unfit for preservation.

The rivers are visited in October and early November, and again in February, March, and April, when the fish are caught in gill-nots set under the ice. Many natives also visit the rivers when they are open in summer and find fish plenty, but bring none home. The species also occurs in summer in the shoal-water bays east of Point Barrow, and is taken rather sparingly in gill-nets at Perguiak, Elson Bay, where we also caught a few young ones in our seine. Captain Herendeen visited the rivers in October, 1882, and brought in several specimens of this species in good condition, with other whitefish.

# 14. COREGONUS NELSONI Bean.

We obtained this species of large size from the rivers, where it appears abundant. It was not obtained at Elson Bay.

#### 15. COREGONUS KENICOTTI Milner.

This species appears to be the most abundant at the rivers, and attains a large size. It was not obtained in Elson Bay.

# SALMONIDÆ.

# 16. SALVELINUS MALMA (Walb.) Jordan & Gilbert.

In the autumn of 1882 we obtained from a native a piece of the dried skin of one of these fishes. He said that he took it in the sea, near the mouth of the Colville River, and that they were so plenty that they fed the dogs with them.

Just as we were preparing to abandon the station in August, 1883, the Eskimos brought in a couple of large specimens of this species which had been taken in the gill-nets at Pergniak. They were a very pale, "sea-run" form, with the spots hardly perceptible.

When we were at Unalaska, in September, 1883, Dr. Wilson, of Lieutenant Schwatka's party, and I found this trout plenty in the stream back of the village. They were rather pale and silvery as if in the habit of running to the sea, and took small, dark flies greedily.

They are also plenty and large in the small lakes at Plover Bay, Eastern Siberia.

# 17. ONCHORHYNCHUS ap.

A large salm in was brought down from Pergniak in July, 1882, but was mutilated and was used for food. The season of 1883 was so backward that we were unable to secure any specimens before abandoning the station.

I suspect this to have been O. nerka.

# 18. ONCHORHYNCHUS GORBUSCHA (Walb.) Gill and Jordan.

This species occurs sparingly in the salt water at Pergniak, Elson Bay, where it is taken in the gill-nets, in July and August.

# IV.-INSECTS.

# INTRODUCTORY-BY JOHN MURDOCH.

The shortness of the summer season rendered the collecting of insects difficult and unsatisfactory, and the difficulty was increased by the engrossing nature of the other zoölogical and physical work of the station. The season at which insects could be collected was precisely the time when the collecting of birds and their eggs was at its height, and the time of the party was pretty fully occupied.

Nevertheless, a small collection of insects was made and turned over to Prof. C. V. Riley, Curator of Insects, U. S. National Museum, for study. As will be seen by his report, which follows, insects were obtained belonging to the following orders and species:

# NEUROPTERA.

Leptocerus sp.
Oligoplectrum morosum?

Urocerus flavicornis,
A Tachinid fly.

#### LEPIDOPTERA.

Laria rossii. An Arctian moth.

# HYMENOPTERA.

Bombus moderatus. Bombus sylvicola.

A species of Podurid and a spider were also turned over to Professor Riley.

The following is Professor Riley's report:

# REPORT UPON A COLLECTION OF INSECTS MADE AT POINT BARROW, ALASKA.

By C. V. RILEY, Curator of Insects, United States National Museum.

No. 1, found swarming around the dead bodies at the Eskimo cemetery, Jane 22, 1882, is a species of Scatophaga and, in all probability, undescribed. It comes nearest to the reddish-haired specimens of *S. stercoraria* Linn., a form common to both Europe and America, but Dr. S. W. Williston, to whom specimens were referred, considers it distinct. The arista is bare, the bristles are fewer, weaker, and shorter, and the cross-veins of the wing are narrowly but strongly clouded. In the twelve specimens examined there is some variation in these respects and in the coloration of the legs. Judging from the known habits of the genus to which the species belongs there can be little question that the larva would be found preying upon dead animal and stercoraceous matter.

No. 2, which is reported rather abundant near the pools all over the tundra, but keeping very quiet except on the occasional calm and warm days, represents three different species of *Chironomus*, most of the specimens too poor to identify. The observations of their habits correspond to the well-known aquatic habits of the genus.

No. 3, taken near the station, June 22, is also a species of *Scatophaga*, showing some points of difference from No. 1, but probably only varietal.

No. 4, found not commonly flying around sunny banks, is one of the Crane-flies (Tipulidae) belonging to the genus *Ctenophora*. There are two species represented by the number, both apparently new. The larvae of these flies dwell in meadows, feeding on the roots of grass.

No. 5, which hatched from a cocoon in the house, is a female, imperfectly developed, of *Laria rossii* Curt., one of the Bombycidæ, common in Europe and North America, and originally described under the genus *Dasychira*. It is a rare species.

No. 8 is an *Anthomyia* that from the soiled material cannot well be identified, but is very near to *A. zew.* Riiey, the habits of which will be found recorded in the first Report on the Insects of Missouri, p. 154.

No. 9, taken June 27, is also a Tachinid identical with No. 6.

No. 10, which was found not uncommon in the dryer and sunny spots in the tundra from May till July, is Amara obtusa Le Conte, family Carab.dw. The species was originally described from Alaska and does not appear to extend further south and east. Among the seven specimens collected, Mr. E. A. Schwarz, to whom I referred them, finds the following variations which are of interest to record though parallel series are known to occur in other arctic Coleoptera. Two specimens have the elytra decidedly more parallel on the sides and consequently the apex more suddenly rounded; the basal punctation of the thorax is well marked in three specimens, while in the remaining four the middle of the base is more or less smooth, the sculpture of the elytral strice is very strong in some and nearly obsolete in other specimens. The color of antennae, elytra, and legs varies from red to piecous.

Under No. 11 there are three different insects: (1) the same Anthomyia included under No. 8; (2) a single specimen of a Neuropterous insect belonging to the Perlid genus *Leptocerus* Leach, very much damaged and unfit for study; (3) a single specimen of another species of crane-fly belonging also to the genus *Ctenophora*, but differing from No. 4, and also, according to Dr. Williston, a new species.

No. 12, taken July 11, 1882, near the house, is *Urocerus flavicornis* Fabr. (family Uroceridæ), a rather small specimen. This is an insect rather widely distributed, and its larva, as is the habit of the genus, doubtless either fed in the stem or trunk of some shrub or tree growing at Point Barrow, or may have issued from timber taken to the Point for building purposes.\*

No. 13, taken along the dryer edge of the tundra, is again an Anthonyid, small, but allied to No. 8, but under the same number there is a single specimen of another Dipteron belonging to the genus Cordylura, and, so far as I have ascertained, undescribed but closely related to C. gilvipes. It belongs to the same family with Scatophaga, and, without doubt, has similar habits. There is also under this number a single, very much damaged, specimen of a Neuropterous insect belonging to the family Phryganidae or caddis-flies. So far as the specimen permits an opinion, it comes near Oligopheetrum morosum McLachlan.

No. 14 contains two different species of Bumble-bees, the one Bombuo moderatus Cresson, the other the common boreal form of B. sylvicola Kirby.

No. 15, found on the shore of the lagoon, is another specimen of the Tipulid genus *Ctenophora* and without much question the female of one of those of No. 4.

No. 16. I find no insect with this number.

end No. †No. 17. A boreal Arctian (-----); also common to Europe and America.

No. 18, caught near the house, is the well-known gad-fly (*Edemagena tarandi* Linn.) of the reindeer (*Cercus tarandus* var. *arcticus*), which suffer much from the larvæ making their way through the skin:

Of the alcoholic material, No. 649, found in the stomach of a bird (Centrophanes lapponicus), belongs to the genus Chrysomela (family Chrysomelide, or leaf-beetles), and appears to be referable to Ch. montivagans Le Conte. Of this particular group of Chrysomela (Chrysomela sens. str.), characterized by the thickened thoracie margin, only a few species are known to occur in North America, in the majority of which the specific characters are very feebly expressed, the number of species thus becoming more or less opinionative. Whether or not the only specimen from Point Barrow is correctly referred to the above species must be left undecided until more complete material from different localities can be compared. Le Conte described montivagans from the high alpine region of Central Colorado, and the typical specimens are much larger and more brilliantly colored than that from Point Barrow.

Most of the species are quite interesting, as is generally the case with species collected in such regions, where proper notes are made in connection with them. The misfortune is, however, that most of the material is too poor for proper specific identification or description. It is for this reason that I do not care to accompany this report with descriptions of the new species, though I may send in descriptions of some of them before the report is published if I can find time to make the necessary critical comparisons. It is preferable, however, to leave them for the present undescribed until such time as some specialist shall work up the particular families or groups to which they belong. There is little gain to entomology in describing such fragmentary material, and it should not be done except where absolutely required.

<sup>\*</sup>The latter is probably the case, as there are no trees or shrubs large enough to maintain the insect growing at Point Barrow,—J. M.

<sup>+</sup>This insect, though perfect when turned in, was accidentally destroyed in the laboratory at the Agricultural Department .-- J. M.

# V.-MARINE INVERTEBRATES.

(EXCLUSIVE OF MOLLUSKS.)

By John Murdoch, A. M., Sergeant Signal Corps, United States Army.

The collections and observations upon which the following report is based were made by the writer and Sergeant Middleton Smith, naturalists and observers, assisted by the other members of the party, especially by Lieut. P. H. Ray, commanding, and Capt. E. P. Herendeen, who took especial care of the dredging and seining operations.

Collecting was attended with considerable difficulty on account of the short season during which the sea was free from ice, but it is believed that the collection gives a fair representation of the marine fauna of the region.

It will be seen to be purely Arctic in character, showing many striking points of resemblance to that of Greenland and the Arctic Ocean of the Old World, and offering but little analogy to the fauna of the North Pacific.

A report on the Medusæ observed by the writer, prepared by Dr. J. W. Fewkes, of Cambridge, has been incorporated with the following, which also includes a description of the few fresh-water invertebrates collected.

The Mollusks have been submitted to Mr. W. H. Dall, of the Smithsonian Institution, who presents a separate report on them.

Vega-Expeditionens Vetenskapliga Iakttagelser, i, pp. 714, 715. A Monograph of the Scal Islands of Alaska, p. 137. Proceedings U. S. National Museum, vi, p. 224.

Two small males were captured in the rich haul of the dredge, made ten miles west of Point Franklin, in 13½ fathoms of water, August 31, 1883. Nordenskiöld found this species very abundant in Bering Strait and in the Arctic Ocean north of the strait. According to Elliott (loc. cit.) this crab is very abundant on the island of St. Paul, of the Pribyloff group, though not found on St. George, and is of great value as an article of food.

The species is well known from Greenland, where it was originally described, Labrador, and as far south on the American coast as New England (in deep water), from Siberia, the Arctic Ocean, and Bering Strait.

The specimens obtained agree in proportions with Stimpson's *C. behringianus*, from nearly the same locality. This species, however, according to Smith, was based on young specimens of *C. opilio*, such as ours are.

The specific name phalangium, originally applied to this species, was rejected by Otho Fabricius himself, on the ground, as he expressly states, that he found it preoccupied by Cancer phalangium J. C. Fabricius (Stenorhynchus phalangium M. Edw.). Having been able to consult O. Fabricius's original description of Cancer opilio, I find that it was published in 1788, which settles the question of priority over C. opilio J. C. Fabricius (1793), and establishes the specific name opilio for this species.

#### 2. HYAS LATIFRONS Stimpson.

Year.	Name.	Citations.		
1857 Hy 1879 Hy	as latifrons, Stimpson	 Proc. Acad. Nat. Sci., Phila., p. 217. Trans. Conn. Acad. Arts and Sci., v, p. 45.	-	

Three large males were picked up on the beach near the station, one dry, in the spring of 1883, and the other two fresh, August 23, 1882. 'One small male was also dredged in 13½ fathoms, on the rich bottom of small pebbles, sand, and broken shells, ten miles west of Point Franklin, August 31, 1883. This crab was well known to the natives of Point Barrow, who called it by the name "Kinaura."

I have carefully examined Dr. Stimpson's types of *Hyas latifrons* in the National Museum, and compared our specimens with them. I find our specimens indistinguishable from Dr. Stimpson's types, and differing from a typical *Hyas coarctatus* from Greenland only in the shape of the rostrum, which is slightly shorter and less acute.

Smith (loc. cit.) pronounces *H. latifrons* a good species, and I have accordingly followed his authority in recording the species.

#### ANOMOURA.

# 3. EUPAGURUS TRIGONOCHEIRUS Stimpson.

		•	 
Year.	Name.	Citations.	
1858	Eupagurus teigonocheirus, Stimpson	Proc. Acad. Nat. Sci., Phila., 1858, p. 240.	

This species was found washed up on the beach near the station in considerable abundance during the months of July and August, after the sea had opened completely. It was also found in the gullet of *Somateria spectabilis* shot near the station. Comparatively few were dredged off Point Franklin in 13½ fathoms, and a few were also dredged at the head of Norton Sound in 5 fathoms on a pebbly bottom.

Our series of specimens have been carefully compared with identified specimens of *E. pubescens* and *E. Kröyeri* from the eastern coast (its nearest allies). The species is very closely related to *E. Kröyeri*, but shows the following well-marked and constant differences in the form and proportions of the chelipeds: Hand of right cheliped in *Kröyeri* twice as long as broad; in *trigonocheirus*, generally less than twice as long as broad, often much less. Outer or right-hand margin of hand in *Kröyeri* slightly concave; in *trigonocheirus* strongly arched, except in very large specimens, almost exactly as in *E. pubescens*. Hand of left cheliped in *trigonocheirus* nearly the same as in *Kröyeri*, but stouter in proportion, and with the outer surface, between the keel and the margin, more concave than in *Kröyeri*.

Stimpson's types of  $\tilde{E}$ , trigonocheirus appear to have been destroyed in the Chicago fire, and consequently the only means we have left of identifying the species is his Latin description (loc. cit.). Our species differs so much from E,  $Kr\ddot{v}ycri$  that it must be considered at least a well-marked variety.

As, however, it agrees so closely with Stimpson's description quoted above, it seems preferable to regard it as Stimpson's *E. trigonocheirus*, especially as Stimpson described the species *Kröyeri* after he had described *trigonocheirus*.

Stimpson gives as the habitat of this species, "In Oceano Arctico et in freto Beringiano vulgaris; sublittoralis, et ad profund. 10-20 org, inventus."

		and the same of th	
1839	Pagurus salendescens. Owen	Zoölogy of Beechey's Voyage, p. 81, pl. xxv, fig. 1.	

This species is easily recognizable by its long, slender left hand, and the beautiful iridescent colors of the carapace and claws.

One small specimen was dredged in 15 fathoms on a muddy bottom off Point Barrow, August 8, 1883. Two other small ones were obtained off Point Franklin in 13½ fathoms August 31, 1883, and six good-sized individuals, four of them females bearing eggs, were dredged with the other Hermit Crabs at the head of Norton Sound in 5 fathoms, September 12, 1883.

Dr. Leonhard Steineger also obtained this species at the Commander Islands.

1883	Hippolyte phippsii, Smith	Proc. U. S. Nat. Mus., vi, pp. 220, 225.

Dredged in considerable numbers off Point Franklin in 13½ fathoms, August 31, 1883. Out of nineteen specimens taken at one haul of the dredge, four were females carrying eggs.

This is a circumpolar species, extending as far south as Massachusetts.

## 12. PANDALUS DAPIFER Murdoch.

(Plate --, fl gs.--.)

1884, Pandalus dapifer, Murdoch. Proc. U. S. Nat. Mus. vii, p. 519.

DESCRIPTION.—Length of carapace (including rostrum) contained about 24 times in total length. Rostral carina beginning about the middle of the carapace, and armed with two or three teeth. Rostrum exceedingly long, nearly 11 times the length of the carapace, slender and tapering. slightly curved up, with 5 to 7 teeth on the upper edge, running only about one third of the length of the rostrum, leaving the rest unarmed to the tip. Lower edge with 4 or 5 teeth, the anterior tooth a short distance from the tip. Eyes large, pyriform, and black. Peduncle of antennule reaches about to middle of antennal scale, and its distal segment is about one-third the length of the preceding. Internal flagellum of antennule slender, reaching nearly to end of rostrum; external about two-thirds as long as internal, much thickened nearly to the tip, where it suddenly becomes slender. Antennal scale a little more than half as long as the rostrum. External maxillipeds long and slender, reaching nearly to the tip of the antennal scale, or about to the middle of the rostrum. First pair of legs very slender, reaching to the tips of the outer maxillipeds. Second (chelate) legs unequal: left very long and slender, reaching to the tip of the rostrum, carpus multiarticulate, with about 25 joints, of which the distal twenty or so are separated by distinct articulations; right leg much shorter, reaching only to the tip of antennal scale, with a carpus of about 7 joints only; distal joint of carpus in each leg equal in length to preceding two, the rest about as long as broad. Right chela a little the larger, both alike otherwise, hardly stouter than the carpus; digits equal, slightly gaping, and a little shorter than the basal portion. Third, fourth, and fifth pairs of legs long and slender, reaching nearly to the tip of the antennal scale. Abdomen rounded above, except the third segment, which is compressed and keeled. This keel is produced into a blunt backward-pointing hook in the male. Sixth segment once and a half as long as the fifth, and equal in length to the telson. Telson rounded at the tip, and armed with three pairs of spines. Dredged in abundance off Point Franklin, in 131 fathoms, August 31, 1883. Museum No., 7881.

## SCHIZOPODA.

# 13. MYSIS RAYII Murdoch.

(Plate -, figs. -).

1884, Mysis rayii, Murdoch. Proc. U. S. Nat. Mus. vii, p. 519.

This was dredged in rather large numbers, not far from the shore, about half a mile above the station, in about 5 fathoms of water, on a bottom of mud and sand mixed, August 13, 1882. Some of the females were still earrying eggs in the brood-pouches. This species belongs to the same division of the genus as *M. vulgaris*, having the telson entire and the antennal scale fringed on both sides with setce. It may at once be distinguished from *M. vulgaris* by the shape of the rostrum, which is quadrangular, with rounded corners.

Description.—Rather slender, with the cephalothorax a little narrower in front than the rest of the body. Carapace of medium length, exposing only the dorsal portion of the last thoracid segment. Rostrum lamellar, quadrangular, with the antero-lateral angles rounded, about as broad as long, reaching half the length of the coular peduncles. Eyes not large, hemispherical; peduncles clavate, stout. Peduncle of antennule about one-third the length of the carapace, bearing two flagella, about equal to the carapace in length. Antennal scale sharply lanceolate, about as long as the carapace, bearing setse on both edges, and armed at the tip with a sharp spine. Antennal about as long as the body. Legs medium, with tarsi of eight or nine joints. Telson about half the length of the cephalothorax, lanceolate, channeled deeply above for its whole length, with apex truncated, entire, and fringed with short stout setse. Uropods long, with the inner lamina as long as the telson, and the outer more than twice as long.

Transparent, with a few arborescent black pigment spots. Length between 60 and 65mm.

The species is respectfully dedicated to the commanding officer of the expedition, Lieut. P. H. Ray, Eighth Infantry, U. S. A., who was superintending the dredging at the time it was taken. Museum Nos., 7880 and 7892.

# CUMACEA.

#### 14. DIASTYLIS RATHKII var.

Two individuals of a large species of *Diastylis* were obtained, one on the beach near the station and one in the rich haul of the dredge off Point Franklin. Both specimens were more or less battered, but as far as can be made out agree very closely with the published descriptions and National Museum specimens of *D. rathkii*, except in having the dorsal keel smooth anteriorly instead of secretard

I have ventured to record these as possibly a variety of *D. rathkii*, which, as is well known, is circumpolar in its distribution, but dare not hazard any further conclusions on account of insufficiency of material.

# 15. DIASTYLIS sp.

#### 16. DIASTYLIS sp

Two other small species of Diastylis were also obtained by the expedition, one close to the station, in  $2\frac{1}{2}$  fathoms of water, and the other off Point Franklin.

I have been unable to identify them with any of the means within my reach, and am inclined to believe that they are undescribed. In view, however, of the difficulty of the group and the insufficiency of the literature at my command, I have concluded to record them simply as above.

1882		749.	

Only three specimens were obtained, and these were washed up on the beach. Stuxberg (loc. cit.) gives the distribution as confined to the northern coast of the Old World, from the Varanger Fjord in the west to Bering Strait in the cast, thence extending down into Bering Sea to Kamtschatka and the Sea of Okhotsk; also in the Baltic, the lakes of Sweden and Russia, the Caspian Sea, the Sea of Aral, and Lake Baikal.

There are, however, many specimens in the National Museum (No. 2430) sent by Macfarlane, from the Anderson River region, thus extending the range much farther to the east. It was also collected by Nelson at Saint Michael's, Alaska.

Zoilogy of the Blossom, p. 92, pl. xxvii, fig. 6. Mem. Boxton Soc. Nat. Hist., i. p. 206, pl. vivi, fig. 6. Further Deep-Sea Dredding in the Gulf of Saint Law rence, p. 15. Proc. Essex Institute, ix, p. 108. Proc. Cal. Acad. Sci., vii, p. 43. Proc. U. S. Nat. Mus., ii, p. 169. Report U. S. Fish Commission for 1878, p. 352. Vega-Exp. Vetensk, lakt., i, pp. 495 et seq. (passim). Proc. U. S. Nat. Mus., vi. p. 231.

This species occurred in very great abundance on the rich bottom 10 miles west of Point Franklin, in 13½ fathoms, and was rather plenty also at the head of Norton Sound, on a pebbly bottom, in about 5 fathoms.

The color when alive is a whitey-brown, clouded with bright crimson, generally forming crimson patches on the terga of the segments and on the edges of the epimera, which sometimes coalesce, forming bars across the head, the middle, and the end of the thorax. The peduncles of the antenna and the middle third of the flagella are bright crimson.

The species was originally described by Owen (loc. cit.) from the "Arctic seas." Packard secured one specimen at Sloop Harbor, Labrador, and it has also been recorded from the Gulf of Saint Lawrence. Two specimens (Lockington's *Idothea pulchra*) were brought by W. J. Fisher from the "west coast of Alaska, north of Bering Strait," and two specimens have been obtained on the Grand Bank of Newfoundland. The Swedish expeditions obtained this species at various points along the northern coast of Siberia from Nova Zembla nearly to Bering Strait.

This species occurred washed up on the beach near the station in considerable numbers in the early part of September, 1882.

Two were dredged just outside the grounden ice in 15 fathoms, August 8, 1883. A few large specimens were also obtained off Point Franklin in 13½ fathoms.

It has been observed in Greenland, Spitzbergen, and Finmark.

# 24. ONISIMUS LITORALIS (Kr.) Bosck.

Year.		Name.	Citations.

This was always rather abundant in the shoal water along the beach. The specimens preserved in the collection floated up in the tide hole with a small dead fish on which they were feeding, March 30, 1883.

This species has been recorded from Greenland, Spitzbergen, Finmark, and the neighborhood of Franz Josef Land. "Rather plenty on the surface of the sea at the edge of the ice, as well as between the pack-ice" (Heller, loc. cit. tr.). The Vega Expedition obtained it on the northeast coast of Siberia, in longitude 177° 28′ E.

#### 25. STEGOCEPHALUS AMPULLA (Phipps) Goës.

(Nev auct, = 8. inflatus Kr.)

Year.	Name.	Citations.
1774 1840 1805 1870 1877 1882	Megacephalus ampulla, thies	Histoire Naturelle des Crustacéos, III, p. 22. Oefv. af K. Vetenak. Akad. Förhandt, xxii, p. 521, pl. xxxviii, fig. 9. (Part.) Forhandt, Videnak. Selsk., p. 123. (Crust. Amplup.) Ann. and Mar. Nat. Hist., ser. 4, x/x, p. 134.

In the synonymy above given I have only quoted such descriptions as can be undoubtedly referred to this species by good figures or otherwise, as two species have been confused under this name. Phipps first obtained it in the neighborhood of Spitzbergen and gave an excellent figure and description.

This form does not appear to have been observed again till the Rev. E. A. Eaton brought it from Spitzbergen, in the summer of 1873, except by Goës, who collected both species at Spitzbergen, but considered the difference as perhaps sexual.

In 1842 and 1844 Kröyer (Nat. Tids., 1 R., iv, p. 156, and 2 R., i, p. 522, pl. 7, fig. 3) established the genus Stegocephalus for an amphipod brought from Greenland, which he called S. inflatus. Most subsequent writers have considered this a synonym of Cancer ampulla Phipps, and Bell (in Belcher's "Last of the Arctic Voyages," ii, p. 406), under the name of S. ampulla, gives an excellent figure of S. inflatus, criticising Phipps's really very accurate figure as a bad one.

Miers (loc. cit.), having obtained the two species from Mr. Eaton, was the first to recognize the difference and to point out the fact that Kröyer's species was distinct from the one described by Phipps. Stegoccphalus ampulla was obtained at many places on the Arctic shore of Siberia by the Vega Expedition, and Stuxberg, overlooking Miers's paper, considered it a new species which he proposed to call S. kessleri though he gave no description but only an excellent figure.

It is quite unlikely that the difference is a sexual one, as suggested by Goës (loc. cit.), because Phipps figures both male and female of *S. ampulla*, and there are besides well marked differences in color between the two species. Moreover, *S. ampulla* has never been obtained in Greenland, or on the eastern coast of North America, where *S. inflatus* is of comparatively frequent occurrence.

Four or five specimens were dredged on the muddy bottom close to the station in about  $2\frac{1}{2}$ 

The species has been found in Spitzbergen, north of Nova Zembla, towards Franz Josef Land, and at several localities during the voyage of the Vega.

Stuxberg (loc, cit.) gives the range of this species as confined to the Old World from Franz Josef Land, Nova Zembla, and Spitzbergen, along the Siberian coast east to Bering Strait. White axes records it from the Gulf of Saint Lawrence.

A few were dredged off Point Franklin in 132 fathoms on the rich bottom.

The species has been obtained in Greenland, Labrador, Grand Manan, Spitzbergen, and the Kara Sea.

# 30. ACANTHOZONE POLYACANTHA Murdoch. (Plate I. fig. 4.)

Vear. Name. Citations.

1884 Acanthozone polyacantho, Murdoch . . . . . Proc. U. S. Nat. Mus., vii, p. 520.

Description.—Head rounded, with a very short, sharp rostram and a small lateral spine at the base of the lower antennae. Eyes round and prominent. Posterior edge of first five segments of pereion raised into a rounded ridge, developing into a median tooth on the fifth segment. Anterior edge of first segment also raised into a similar ridge, curving forward over the head. Last two segments of pereion and first four of pleon armed on the posterior edge with a large broad median tooth pointing backwards, largest on the third segment of the pleon, and very small, almost obsolete on the fourth. The last two segments of the pereion and the first two of the pleon also carry a small accessory tooth midway between the median tooth and the epimeral suture. The epimeral suture bears a deep lateral keel which becomes a sharp, posterior, backward-pointing tooth on the last two segments of the pereion and the first four of the pleon. The infero-posterior

angle of the epimeron bears a spine (there are two on the second segment of the pleon). Upper antenne about two-thirds the length of the lower. Gnathopods slender, subchelate. Telson rather long, entire.

A few specimens were dredged off Point Franklin, in 13½ fathoms, August 31, 1883, Museum No. 7898.

## 31. ATYLUB SWAMMERDAMII (M. Edw.: Sp. Bate.

1		regimen referr +	
1	fear.	Name	Utations

	FR FRE A			
Year.	Name.	1	Citations.	
1884 Melita formosa,	Murdoch	, Proc. U. S. Nat. Mus., vii.	p. 520.	

This species is very close to M. obtusata, but may be distinguished by the shape of the nail of the second gnathopods.

DESCRIPTION .-- Antennules with the first joint of the peduncle not quite as long as the second.

and.

gen.

ranz hite-

the

e at ents uteast oad

iost ilso The ing ior Two anterior segments of pleon with infero-posterior angle acute; third segment with this angle acute and produced upwards. Second and third segments of pleon armed with a single tooth each on posterior margin, fourth with three, fifth with four teeth, all very small. Hand of first gnathopod oval and fringed with long hairs on the posterior margin. Hand of second gnathopod in male broadly oval, and armed on the edge with 3-4 blunt teeth and running out into a broad, blunt tooth; claw large, curved, and acute, shutting on the inside of the palm. Inner ramus of the last pair of saltatory feet ovate. Color purple with a lighter streak down the middle of the dorsal surface.

Picked up on the beach near the station in considerable numbers, late in the summer of 1882. Museum numbers, 7893, 7894, 7895.

# 34. MELITA LEONIS Murdoch.

(Plate II, figs, 2, 2b.)

Year.	Name.	1	Citations.	
		_		
1884   Melita i	leonis. Murdeeh	Proc. l*. S.	Nat. Mus., vii, p. 521.	

This species is closely allied to *M. dentata*, but differs in the dentition of the segments of the pleon, and in the length of the antennules.

DESCRIPTION.—Eyes small, oval, black. Antennules reaching to the first segment of the pleon, with the first joint of the peduncle a little shorter than the second. Third segment of the pleon with the infero-posterior angle acute and produced upwards. First and second segments of the pleon with one large median tooth on the posterior edge and eight fine denticulations, the latter larger on the second segment; third with nine teeth, of which the median one is the largest fourth with five; fifth with six, lacking the median tooth; sixth with two small, blunt teeth. Hand of first gnathopod with infero-posterior angle of third joint not produced into a tooth; hand elongate-oval, edge rot toothed. Color purple, with two lighter streaks along the dorsal surface.

I have named this species from the schooner Lee of San Francisco, from which vessel the specimens were obtained, by dredging in about five fathoms of water at the head of Norton Sound, September 12, 1883.

Museum numbers, 7893, 7897.

A few were taken at Pergolak (in Elson Bay) among seaweed dragged up by the seine, August 11, 1853, and some were also picked up on the beach late in the summer of 1882.

It has been observed at Prince Regent's Inlet, Arctic America, abundant (Sir J. C. Ross) in the "Arctic Scas" (Sir Edward Parry and Sir Edward Belcher) and Greenland (Kröyer, quoted by Spence Bate). Beeck (loc. cit.) gives as its habitat "Grænlandia, Spitsbergia, in lacubus Finlandia, et Svecia et Norvegia."

The Vega expedition obtained it at various points along the Arctic coast of Siberia from Nova Zembla nearly to Bering Strait.

# 36. DULICHIA ARCTICA Murdoch.

(Plate II, fig. 3.)

Year.	Name.	Citations.	
1881	Dutichia aretica, Murdoch	Proc. U.S. Nat. Mus., vii, p. 521.	

DESCRIPTION.—Head slightly produced, forming an obtuse angle. First epimeron produced into a sharp spine projecting forward, the rest unarmed. Body smooth. Basa of second gnathopods dilated and armed with two teeth; hand large, subtriangular, and armed on the edge with two long, stout teeth. Last three pairs of perciopods not specially long; third joint as long as the fourth and fifth together. Second pair of saltatory feet with outer ramus nearly twice as long as the peduncle; inner a little longer. Eyes small, round, and black. Color grayish.

Dredged in rather small numbers off the station in 5 fathoms on a muddy bottom, Museum numbers, 7899, 7900.

# PHYLLOPODA.

# 37. LEPIDURUS GLACIALIS (Kr.) Baird.

Year.	Name.	Citations.
1852	Lepidurus glacialis, Baird	Nat. Tids., if R., II, p. 431; Voy., pl. 40, fig. 1. Monograph of the family Apodidae. Proc. Zoo. Soc. Lond., pl. xx, p. 6; Annulosa, pl. xxii, fig. 2.
1878	Lepidurus glacialis, Packard	Phyllopods of N. America. Report of U. S. Geological and Geo- graphical Survey of the Territories, pt. i, p. 316.

This species has been kindly identified by Dr. A. S. Packard, jr., of Brown University, who examined our specimens and compared them with a specimen from Greenland.

It was abundant on the pools on the tundra, where it lurked in the mud and alga, but appeared slightly capricious in its distribution, as it was not found in every pool. They lived until the pools froze up in the autumn.

They were especially abundant in the pool near the station from which we obtained our drinking water. In 1882 they were observed for the first time on July 8, but the next year they were ten days later in appearing, and seemed scarce and sluggish.

The species has been obtained in Greenland and also near Cape Krusenstern, Alaska.

# 38. BRANCHINECTA PALUDOSA (Müll.) Verrill

Year.	Name.	Citations.

It has been found in Greenland and Labrador and at Cape Krusenstern, Alaska. (See Baird, loc. cit.)

Dr. Packard has kindly examined these specimens, and says that they do not differ from those brought by Dr. Bessels from Polaris Bay.

#### 39. POLYARTEMIA HAZENI Murdoch.

(Plate 11, figs. 1 16.)

Year.	Name.		Citations.	
1884	Polyartemia hazeni, Murdoch	Proc. U. S. N.	at. Mus., vii, p. 522.	

Specimens of a species of Phyllopod, found in abundance near the station, were examined by Dr. Packard, who declared that they belonged to the genus *Polyartemia*, but were different from the single species (*P. forcipata*) of this genus, described by Fischer in Middendorff's Sibirische Reise, ii, pt. i, p. 454, pl. vii, figs. 24–28 (1851).

I therefore decided to describe this as a new species under the name of *Polyartemi hazeni*, after General W. B. Hazen, Chief Signal Officer, U. S. A., to whom the species is respectfully dedicated.

Description,—Body long (twice the length of the abdomen) and stout. Legs generally seventeen pairs, males usually with one pair more than the females. Head in the male prolonged anteriorly into a short, thin, lamellar process. Male "claspers" large, stout, broad, and palmate, strongly incurved. From the middle of the lower edge projects a large curved process armed on the tip and inner surface with numerous fine teeth. The extremity of the "clasper" is bifurcated into two short, blunt branches, also armed on the inner side with fine teeth. Feet short and broad-Cau lal appendages small and slender, a little longer than the last abdominal segment. Ovisae voluminous, nearly as long as the abdomen; end rounded, with a short, tooth-like process on each side. Color, when living, a pale, iridescent green.

Museum numbers, 7929, 7930, 7931.

The species was first observed July 13, 1882, in large numbers, copulating, in the pools on the black fundra.

It is not so widely distributed as Branchinecta paludosa, which occurs in the same pools. It swims very swiftly and is very hard to eatch.

# CIRRIPEDIA.

# 40. BALANUS sp.

Small barnacles were quite plenty on gastropod shells near the Pation, and a single large one which I cannot identify was dredged off Point Franklin. (This is probably B. norcetus).

Two specimens were dredged with the other *Polynocs* off Point Franklin, in 13½ fathoms, August 31, 1883.

This species has been united with *P. scebra* by Wirén (loc. cit.); but the specimens we obtained agreed so closely with Hansen's description, and differed so much from our specimens of *scabra*, that I have concluded it best to record it as a distinct species.

It was originally described by Hansen from specimens taken in the North Atlantic.

# 3. POLYNOE SARSI (Kinberg) Théel.

1883	Nephthys coca, Wiren	Vega-Exp. Vetensk. Iakt., ii, p. 392, pl. 30, figs. 1-3; pl. 31, figs. 1-

Two good-sized specimens and four smaller ones of the *ciliata* type and two medium individuals of the *longisetosa* type were dredged near the station, in about 3 fathoms, on the muddy bottom.

One smaller specimen of the *longisetosa* type was also obtained near the head of Norton Sound, in 5 fathoms, on a pebbly bottom.

It has been recorded from Labrador, Greenland, Norway, Spitzbergen, Nova Zembla (and northward toward Franz Josef Land, where it was obtained by the Austrian Expedition), and the Arctic coast of Siberia as far round as Saint Lawrence Bay. It also occurs on the British coast.

#### PHYLLODOCEIDÆ.

# 7. ETEONE ap.

A single specimen of a species of *Eteone*, in such bad condition as to render the specific determination impossible, was obtained near the station in 2½ fathoms.

## 8. PHYLLODOCE GROENLANDICA Oersted.

Year.	Name.	Citations.
1867	Phyllodoce grenlandica, Malmgren	Ann. Polych., p. 21, pl. ii, fig. 9.
1875	Phyllodoce grenlandica, Malmgren	(Nominal list.) Arctic Manual, p. 169.
1877	Phyllodoce grenlandica, Littken	Trans. Liun. Soc. London, ser. 2, i, p. 502.
1878	Phyllodoce grenlandica, McIntosh	Denksehr, d. K. Akad, d. Wiss., xxxv, p. 395
1882	Phyllodoce grenlandica, v. Marenzeller	Den Norsk, Nordhafa Esp., p. 31, pl. iii, figs. 21-23.

A bait set at the bottom of the tide-hole, in about 3 fathoms of water, on May 26, 1883, brought up a large number of these worms. They varied a good deal in color when alive, some being red-H. Ex. 44—20

dish and some dark green. They were also dredged on the muddy bottom near the station August 9, 1883, in about 3 fathoms.

It is quite possible that *P. arctica*, described by Hansen (loc. cit.), from the neighborhood of Spitzbergen, is only a variety of this species, as the distinction is based on the number of papilla on the evaginated proboscis, which appears to be subject to great variation.

Among our specimens the same animal has been found to have twelve papillae (characteristic of granlandica) in one row, and fifteen (characteristic of granlandica) in another.

The species has been recorded from New England, Labrador, Greenland, Norway, Spitzbergen, between Nova Zembla and Franz Josef Land, and the Kara Sea.

## 9. PHYLLODOCE sp.

A single specimen of a species of *Phyllodoce*, evidently not *P. granlandica*, but too much mutilated for specific determination, was dredged near the station in about 3 fathoms.

# HESIONID.E.

#### 10. CASTALIA MULTIPAPILLATA Théel.

Year.	Name.	Citations.
1879	Castalia padtiparillata. Therl	K. Svenska Vetensk, Akad, Handl., xvi, No. 3, p. 38, pl. iii, fig. 38.

A few very small specimens of this species were caught in the towing net set under the sea-ice about the end of March, 1883.

Théel described the species from specimens obtained at Nova Zembla.

## SYLLIDÆ.

# 11. AUTOLYTUS sp.

We obtained males and egg-bearing females of a small species of *Autolytus*, which cannot be more accurately identified, swimming free under the ice about the end of March and the first of **A**pril, 1883. The "stem-form" was not obtained.

#### · ARICHD.E.

# 12. ? ARICIA ARCTICA Hansen.

Marine Comment		
Year.	Name.	Citations
4.000 4.0	Commentary of the Manager	Ban Vand Vandhara Fan ali Zallani a 91 alia dia na na

A fragment of a worm of this family, lacking both head and anal end, was obtained off the station, in about 3 fathoms, August 7, 1883. The body segments agree very well in the shape of the feet, gills, &c., with Hansen's figures, but as we were unable to obtain the characteristic hooked ventral seta of the anterior region of the body, the species cannot be positively identified.

It was originally described from near the island of Jan Mayen.

 $\Lambda$  single specimen of this species was obtained close to the station in about 3 fathoms on a muddy bottom.

It has been observed in Greenland, Iceland, Scotland, Western Scandinavia, Spitzbergen, Nova Zembla, and near the winter quarters of the Vega.

#### TELETHUSEÆ.

#### 14. ARENICOLA GLACIALIS Murdoch.

Year.	Name.	Citations.	1
1884	Arraicula alacialis, Murdoch	Proc. U. S. Nat. Mus., vii, p. 522.	

This species is closely allied to *Arenicola marina*, but has only 6 setigerous segments anterior to the gills, and 11 gill-bearing segments instead of 7 and 13, as in *A. marina*. These numbers are constant in the five specimens obtained.

The 6 abranchiate segments are each composed of 5 distinct annulations, and each bear a pair of simple tubercular feet. The dorsal setæ are all of one kind, about 18 in number; slender and slightly serrulate, the longest longer than the foot. The ventral setæ are 35 to 40 in number, and form a single row on each side of the ventral surface of the ring. They are short, slender, and simple, and barely project above the surface of the skin.

The branchiate segments are each composed of 6 annulations. Each branchia consists of one cluster of about 15 simple cirri annulated in contraction. The branchia increase in size from the first to the ninth pair: the tenth and eleventh pairs are slightly smaller. The feet are small and tubercular; the dorsal seta, 7, similar to those of the abranchiate segments, but only about two-thirds of their length. The ventral setae are the same as in the abranchiate segments.

The caudal portion is about one-third of the length of the animal, without tubercles or other appendages.

Color, in alcohol, blackish gray, lighter on the ventral surface.

Five specimens were picked up on the beach, after a fresh westerly wind, September 12 and 13, 1882.

A couple of mutilated specimens were also obtained from the gullet of an eider-duck which had been diving on one of the sandy patches in about 3 fathoms just above the station.

Museum Nos., 851, 854.

1875	Brada granulata, Lütken	(Nominal list.) Arctic Manual, p. 172.	
1883	Bradu oranulata, Wiren	Vega-Exp. Vetensk, Iakt., ii, p. 408.	

This species was dredged in considerable numbers near the station, in about 3 fathoms, in August, 1883.

It has been recorded from Greenland, Spitzbergen, and the northern coast of Siberia near the month of the Taimyr River (Vega Expedition).

# MALDANIDÆ.

16.

A long Maldanid worm, of a bright orange scarlet color when living, was dredged on one of the patches of mud and sand close to the station, in about  $2\frac{1}{2}$  or 3 fathoms of water, August 7, 1883. The only specimen preserved is a fragment of the body without either head or tail, and cannot be identified.

## AMPHICTENIDÆ:

## 17. PECTINARIA Sp.

A good many empty tubes of a species of *Pectinaria* were dredged on the muddy bottom just outside the grounded ice, in about 15 fathoms, and near the station on the sandy patches in about 3 fathoms. No living specimens were taken.

This is perhaps P. granulata, as this species was obtained by the Vega Expedition as far east as Saint Lawrence Bay.

# GEPHYREA.

# ECHIURIDÆ.

# 18. ECHIURUS VULGARIS (Savigny) Forbes.

	- Control of the Cont	* A * * * *	
Year.	Name.	C	itations.
-			
	Thalassema vulgare, Savigny. / Echiurus sitchemsis, Brandt Echiurus vulgaris, Forbes. Echiurus pallasii, Diesing. Echiurus pallasii, Quatrefages	History of British Star-fishes Revision der Rhyngodeen, Si xxxvil, p. 775.	tzungs-berichte d. K. Akad. d. Wiss.

The specimens of *Echiurus* brought home by the expedition cannot be distinguished from the description of *E. pallasii* (= *E. rulgaris*) given by Quatrefages (loc. cit.).

This species has heretofore been recorded from Great Britain and France. Brandt's description of E. sitchensis (loc. cit.) is not sufficiently detailed to enable me to tell whether it is the same species or not.

This worm was quite abundant on the beach, near the station, after the great gales of September and October, 1881, and two specimens were dredged on the muddy bottom, in about 3 fathoms of water, August 9, 1883.

#### SIPUNCULIDÆ.

#### 19. PHASCOLOSOMA sp.

A good many specimens of a species of *Phascolosoma* were dredged near the station in about 3 fathoms of water. They are so badly contracted in alcohol as to entirely disguise the specific characters. I was able to determine by dissection that they belong probably to the genus *Phascolosoma*, but could make out nothing further.

# NEMATODA.

# CILETOGNATHA.

#### 20. SAGITTA Sp.

A species of Sagitta occurred very rarely in the neighborhood of the station. One or two specimens were caught in the towing-net set under the sea-ice March 1, 1883. A few were also observed after the sea opened in August, 1883.

# ECHINODERMATA.

# HOLOTHURIOIDEA.

# 1. PENTACTA FRONDOSA Jæg.

This species was dredged in abundance off the station, on the muddy bottom, interspersed with patches of mud and sand mixed, in  $2\frac{1}{2}$  to 15 fathoms.

It has heretofore been reported from Greenland (Steenstrup, Lütken), Labrador (Packard), and Nova Zembla (Stuxberg). [? Wellington Channel (Sutherland).]

Lütken considers the *Chirodota brevis* of Huxley to be this species, but Danielssen and Koren consider that as Huxley in his description says pothing of the calcareous wheels being pedanculated it must be considered as a distinct species (= Oligotrochus vitreus M. Sars), for which they propose the name Myriotrochus brevis.

	1861	Molpadia borcalis, M. Sara Molpadia borcalis, M. Surs Trockostoma (Molpadia) borcale, Daniels- sen and Koren.	Forhandl, I Vidensk, Selsk, i Christiania, p. 173. Oversigt af Norges Echinodermer, p. 116, pls. 12, 13. Den Norsko Nordhavs-Expedition, vi. Zeölogi, p. 64, pl. x. figs. 7-11.

A single specimen was picked up on the beach near the station, in July, 1882. The perforated calcareous plates appear to have the perforations smaller in proportion than those figured by Sars and Danielssen and Koren, but in the absence of more specimens, and especially of identified material for comparison, I cannot venture to pronounce it different.

The species has been recorded from the Norwegian coast and the North Atlantic, Molpadia violacea, which occurs in large numbers off Kerguelen Island, is considered by Dantelssen and Koren (op. cit., p. 65) to be identical with this species.

A few dry tests were picked up on the beach near the station, during the summer of 1882. The living animals were dredged in very great abundance off Point Franklin in 13½ fathoms, and were also quite abundant off Port Clarence, in 7½ fathoms, on a pebbly bottom. A few were also taken in about 5 fathoms, on a similar bottom, at the head of Norton Sound.

This species is abundant all round the northern parts of both hemispheres.

## Asterioidea.

#### 6. ASTERIAS ACERVATA Stimpson.

Year	Name.	Citations.	
1862	Asterias avervata, Stimpson	Proceed, Boston Society of Natural History, viii, p. 271.	

Rather small specimens of this species, 3 or 4 inches in diameter, were washed up on the beach in considerable numbers after the great gale of October 4, 1881, but none were afterwards found in any of our dredging near the station. One large individual, however, was dredged at the head of Norton Sound, in 54 fathoms, on a pebbly bottom.

This species was described by Stimpson from specimens brought by the North Pacific Exploring Expedition from Bering Strait and the Arctic Ocean north of the Strait. My specimens have been compared with one of Stimpson's own identification in the National Museum.

# 7. ASTERIAS VIOLACEA O. F. Müller.

		· · · · · · · · · · · · · · · · · · ·

			1.1
1841	Asterias violacea, O. F. Mütler Uraster violacea, Forbes Asteracanthion violaceus, Mutler and Tro-	British Startishes, p. 91.	į

Numbers of a large purple Asterias were dredged in about 5–fathoms, on a pebbly bottom, at the head of Norton Sound.

I refer it with extreme doubt to this species as I have been unable to see any identified specimens of *violacea* or *rubens* and the literature at my command is exceedingly unsatisfactory.

The species will probably turn out to be undescribed, but I do not feel sufficiently familiar with the group to venture on a description. It is undoubtedly closely allied to the common European forms *rubens* and *riolacea*, if, indeed, the latter be a distinct species.

## 8. ASTERIAS sp.

A few specimens of a small Asterias with five arms were dredged in about 7 fathoms, on a pebbly bottom, off Port Clarence. They undoubtedly belong to the genus Asterias, but the species is not determinable with any means at my command.

## 9. LEPTASTERIAS ARCTICA (Stimpson).

On Point Franklin, in 13½ fathoms, we dredged large numbers of a small starfish which cannot be distinguished from a dried specimen in the National Museum, brought from Bering Strait by the North Pacific Exploring Expedition and labeled in Dr. Stimpson's handwriting Asterias arctica yar. a. I have been unable to find a published description of this species.

The size and position of the papulæ on the back and sides of the arms show that it belongs to Verrill's genus Leptasterias.

The following is a description of the species: Rays five, rounded above, clongated, tapering regularly to the tips. Radia as 1:3.5. Disk small, its radius about equal to width of ray at base. Interambulaeral spines round and slender with rounded tips, usually two to each plate. No small spines between these and the ventral spines. Ventral spines form a double row of alternating spines, of which the upper are the smaller and the lower are larger and stouter than the interambulaerals. Lateral spines rather slender, forming a single row. No well-marked dorsal row, though the spines in the middle of the arm are rather the larger. The dorsal spines are short and stout, with rounded, almost capitate, tips. The spines of the disk are rather smaller than those of the arms and are arranged irregularly. The major pedicellariae could not be well made out, but appeared to be lanceolate and not numerous. The minor pedicellariae form close wreaths around the spines.

Diameter of the largest specimen about 75mm.

## 10. CRIBRELLA SANGUINOLENTA (Mill.) Ltk

Oversigt af Norgos Echlinodermer, p. 14. (Nominal Pal Arctic Manual, p. 185. Vidensk Meddel, xxili, p. 307. (Nominal Pal Arctic Manual, p. 185. Denkselv, d. K. Akad, d. Wisse, xxxv, pp. 359, 385. Oety, af K. Vetensk, "Akad, Grithandl., xxxv, p. 36.

We found this species very abundant and of large size off Point Franklin in 13½ fathoms. The specimens brought home are indistinguishable from O. aculeata from the New England coast, except for the fact that the small deciduous spines on the dorsal surface of the disk are a trifle larger and more numerous, and the skin round the mouth and on the under surface of the arms appears a little thicker.

This occurrence indicates a circumpolar distribution for the species. It would have been natural to suppose that the allied Pacific-coast species, O. Kennerlyi Lyman, would be found extending up from the temperate regions into the Arctic Ocean, as O. aculeata does on the Atlantic side.

The occurrence of this Atlantic form in this part of the Arctic Ocean may be compared with the occurrence at Point Barrow of two species of birds (Pelidna subarquata and Actodromas fuscicollis) heretofore supposed to be confined to the eastern coast of the continent.

O. acadeata occurs abundantly on the coast of New England, Newfoundland, the Gulf of St. Lawrence, Labrador, Greenland, Iceland, the Faroes, Norway, the Baltic, the British Islands, Spitzbergen, Nova Zembla (and north towards Franz Josef Land), and the Kara Sea as far east as longitude 65° 35′ east. (Swedish Expeditions.)

	programme and the second second	
Year.	Name.	Citations.
1855 1846 ( 1863 1865	Alegonium rubiforme, Verrill Peroname rul forme, Verrill	Zoöphytes, U.S. Exploring Pyp dition, p. C25. Mem. Bost. Society Nat. Hist., i. p. 4. Proc. Essey Inst., iv, p. 190.

This species was found washed up on the beach in considerable numbers after gales of wind, while the sea remained open. It was dredged in great abundance on the rich ground west of Point Franklin, in 13½ fathoms. Two small specimens were obtained on a pebbly bottom off Port Clarence, in 7½ fathoms. September 4, 1883, and one large and very pale specimen same from a similar bottom at the head of Norton Sound, in 5 fathoms. We also obtained this species on our fishinglines when catching codifish in about 25 fathoms of water off the entrance to Plover Bay, Siberia, Its color when fresh is a bright strawberry red.

The species has been recorded as occurring in the Arctic Ocean north of Bering Strait, and on the west coast of the strait (North Pacific Exploring Expedition), also Semavin Strait (Brandt). It also occurs on the banks of Newfoundland, where it is known to the American fishermen as "sea strawberries," according to Capt. J. W. Cohins, of the U. S. F sh Commission, and in the Northern seas of Europe.

Aleyonium sp., mentioned in the Vega-Expeditionens Vetenskapliga lakttagelser, i, as occurring in the Siberian Arctic Ocean, probably refers to this species.

Notes on Radiata, from Trans. Conn. Acad. Arts and Sci., i. p. 469  (teprint 184)-70.

The large sea anemones brought home by the expedition belong, in all probability, to this species, as well as can be made out from alcoholic specimens. The color, when living, varied from bright orange-red to crimson, frequently in splashy stripes on a paler ground.

Large numbers were washed ashore during the great gale<sup>c</sup> in the autumn of 1881, and they were occasionally picked up on the beach during the season of open water of 1882. They appeared to be rather plenty on what was called the "fishing-ground," a place about two miles from the shore, where the natives were catching polar cod through the ice in 10 to 15 fathoms of water. A few large ones were dredged off Point Franklin, in 134 fathoms.

This species is circumpolar in its distribution, and is recorded from Greenland, Norway, Iceland, England, the east coast of North America as far south as Cape Cod, Bering Strait, Sitka, Puget Sound, and the Arctic Ocean between Nova Zembla and Franz Josef Land.

18	Rectif directed, Verrin	i], (reprint 1869-70).	

Several specimens of a rather small polyp, with a rough thickened epidermis and covered with grains of sand, were dredged off the station, in from 2½ to 5 fathoms, especially on the patches of mad and sand mixed.

All the specimens have the disk and tentacles retracted, and are much shrunk in the alcohol, so that identification is practically impossible.

They are very likely to belong to this species, which was described by Verrill from a single specimen brought home by the North Pacific Exploring Expedition from the Arctic Ocean north of Bering Strait, in 30 fathoms of water.

A species of *Pheilia*, which is probably the same as this, was obtained by the Austro-Hungarian Expedition, in 1873, during their drift between Nova Zembla and Franz Josef Land.

A third species of Actinoid polyp also occurred on the beach in large numbers among the large sea apemones. Specimens were obtained, but were spoiled in the attempt at preservation. In contraction, it appears to be devoid of a sucking disk at the base, and takes a spherical form. The color is white and translucent like pure parafine, and the radiating septa are visible through the walls, giving it the appearance of a large gooseberry.

## Chrysaora melanaster BEANDI

Umbrella flat, disk-shaped; radius, a little more than height; diameter, 1 foot. Aboral surface marked with 16 radial stripes of brownish color; 32 marginal lobes, each rounded and destitute of marginal teeth. Sense lappets slightly broader than the tentacular. Oral arms 4 in number; length, 3%; stout at common origin, tapering to pointed extremity, and abundantly fringed with folds on inner margin. Sense bodies, 8. Tentacles, 24; length, 3%. There are 3 tentacles between each pair of sense bodies. Color, bell, mouth-arms, light brown; radial stripes of the umbrella darker; tentacles, dark brown; frills on the oral arms, reddish. Locality, Pomt Barrow. Taken in August, 1883.

From the colored sketches it is not difficult to distinguish this species as *C. melanaster*. Of other species which the drawings resemble might be mentioned the closely-allied *C. helcola* Brandt. They differ from the latter in not having teethed marginal lappets, in the tentacles being shorter (in helcola they are as long as the mouth-arms), and in the colors. The colors agree more closely with those of *C. melanaster* than of helcola. There are, however, several differences. The varieties of color in *C. mediterranea* from different localities have been described by Haeckel, and, considering the great variation which he has shown to exist in the same species, we must not lay any great stress on differences of color as a distinguishing feature of different species of *Chrysaora*.

The species (C. melandster), according to Brandt, is never "less than a foot in diameter" (meaning, of course, the adult). Mr. Murdoch's drawings, therefore, represent small, perhaps young, specimens. The sixteen accessory, small, marginal lappets, which in older forms differentiate themselves from the sixteen ocular lappets, are not represented in the drawings. We may account for their absence from the youth of the specimens drawn.

#### Water attend Dame

Since the original description of this species by Eschscholtz in 1829 it has never been reobserved. The locality from which the specimen which he described was taken is 34° N. lat., 201° W. long., North Pacific.

Eschscholtz described two species of £gina, A. rosca and A. citrea. The £gina collected by M1. Murdoch resembles more closely the descriptions of the latter.

Alexander Agassiz, in "North American Acalepha," described from Nahant, Mass., a new genus of hydroid jelly-fishes, which he called Campanella (sp. pachyderma); this genus is referred by Haeckel to Ægina, under the name of A. pachyderma. The anatomy of Campanella is very different from that of Ægina, and unless, with Haeckel, we regard these differences, following Alexander Agassiz's descriptions, as "Beobachtungs fehlern," we can hardly look upon the two as belonging to the same genus. If Campanella is generically different from Ægina, it is necessary to substitute the name Æginaria Haeckel for it, since, as Haeckel has well observed, Campanella was applied in 1820 to an Infusorian. A new description is necessary before we can certainly know that Æginaria is generically different from Ægina.

Of other species of \*Egina, A. rhodina Haeck, and A. Canariensis Haeck, were found in the Canaries, and A. Eschscholtsii Haeck, in the Azores. The six known species, according to Haeckel, "gehören sämmtlich der wärmeren Zone der nördlichen Erdhälfte." Mr. Murdoch's observation of A. citrea in the Arctic Ocean shows, however, that the genus has a wider distribution as far as

temperature is concerned. Considering, as Haeckel does, that "Campanella" is a species of Egina, his remarks on its limitations in distribution do not hold, for the distribution as known when "Das System der Medusen" was written. The only locality where "Campanella" has been taken is Nahant, Mass., which certainly is washed by cold waters and belongs to the colder zone. It is a significant fact that "Campanella" has never been taken in the bays south of Cape Cod, where the water is much warmer. The meduse of Massachusetts Bay are those characteristic of colder waters, while those of Narragansett Bay, which is south of Cape Cod, belong to the warmer zone of the North Atlantic. "Campanella" is found in the colder waters, and systematic fishing for a number of years in the latter locality has never brought it to light.

Locality.-Cape Smythe, Alaska.

Aglantha camtschatica HAECK.

The figures add a little to our knowledge of this species. Alexander Agassiz, in his description (North American Acalephae) of the same from Galiano Island, Galf of Georgia, says there are from 40 to 48 tentacles. Mr. Murdoch's notes record "96 tentacles." The "three-lobed manubrium," mentioned in the same notes, must have been observed in an abnormal specimen (normally there are never less than four lobes).

# HYDROZOA.

# HYDROIDA (Trophosomes).

The Hydroid Medusae observed by the expedition have been described above by Mr. Fewkes. The following species of Hydroids are represented in the collection by their trophosomes.

## 1. SERTULARIA VARIABILIS S. F. Clark.

-			
Year.	Name.	Citations.	
1876	Sertularia variabilis, S. F. Clark	Scientific Results of the Exploration of	Alaska, i, p. 17, pl. viii,
1		tigs, 40-48, pl. ix. tige, 49, 50.	
			I

One large cluster and some fragments were diedged on a pebbly bottom in 5 fathoms near the head of Norton Sound.

Clark has described the species from various points on the coast of Alaska, both from among the Aleutian Islands and from Bering Sea.

#### 2. SERTULARELLA TRICUSPIDATA Hincks.

Year.	Name.	Citations.
1874	Sertularella tricuspidata, Hincks Sertularella tricuspidata, Kirchenpauer Sertularella tricuspidata, Lütken Sertularella tricuspidata, S. F. Clark	(Nominal list) Arctic Manual, p. 190.

This was dredged in very great abundance off Point Franklin, in 134 fathoms.

It has been recorded from the Aleutian Islands and the Shumagins, and also from Greenland,

#### 3. THUIARIA CYLINDRICA S. F. Clark.

Year.	Name.	Citations.	
1876	Thuiaria cylindrica, S. F. Clark	Scient. Ros. of Expl. of Alaska, i, p. 22, pl. x, fig. 57.	1

Several specimens of a *Thuiaria* were dredged off Point Franklin in 13½ fathoms, which I refer with some doubt to this species.

It differs from Clark's types in the National Museum in having the longitudinal rows of hydrothecae less obvious, and the apertures of the hydrothecae directed alternately in opposite directions.

This species was originally described from the eastern shores of Bering Sea.

# 4. TUBULARIA sp.

A good-sized species of *Tubularia*, closely resembling *T. indivisa*, but apparently having more numerous oral tentacles, and of a bright crimson color, both stem and head, was quite abundant on the patches of mud and sand mixed, close to the station, in 24 to 3 fathoms of water.

# TUNICATA.

#### Ascidiacea.

#### ASCIDIA: SIMPLICES.

# 1. ? BOLTENIA sp.

Several large *Boltenias*, in form closely resembling the ordinary *B. bolteni* of the Atlancic coast, were found washed up on the beach October 13, 1881, after a heavy westerly gale. They were a brilliant red in color.

The same (?) species was also dragged up by the cod-lines in about 18 or 20 fathoms of water off the mouth of Plover Bay, Eastern Siberia.

#### 2. º MCLGULA sp.

A small round Ascidian, always covered with sand, and probably a species of Molgula, was dredged in considerable numbers on the patches of mud and sand mixed, in about 2½ fathoms, close to the station.

## 3. HALOCYNTHIA PYRIFORMIS (Rathke) Verr.

Year.	Name.	Citations.
1780 1788 1842 1871	Ascedia pyriformis, Möder	Faun, Greenl., 322 (teste Lütken).  Nova Acta Petropolitana, ii, p. 246, pl. vii, fig. 38.  Nat. Tids., i R., iv, p. 95.  American Journal of Conchology, vii, nt. 2, p. 157.

A single rather small specimen of this species was picked up on the beach near the station. Mr. Dall found it of large size and brilliant coloring at Plover Bay, Eastern Siberia, and at Petropaulovsk, Kamtschatka.

It is recorded on the eastern coast of North America from Massachusetts Bay to Greenland, and also from Norway.

Pallas (loc. cit.) records it from the Kurile Islands, but the specimens of *Lophothuria fabricii*, in association with which this species was brought to him, are believed to have come from St. Paul's Island. Bering Sea.

#### THALIACEA.

#### 4. ? SALPA HERCULEA Dall.

Year.	Name.		Citations.	
[ 1871   Salpa he	reulea. Dall	American Journ	al of Conchology, vii, pt. 2, p. 158.	

As we approached the Aleutian Islands in August, 1881, we observed many enormous solitary Salpw, 4 or 5 inches in length.

Judging by their size and the red color of the viscera, they probably belong to the species provisionally described by Mr. Dall as above.

# LARVACEA.

#### 5. APPENDICULARIA sp.

From August 8 to 15, 1883, the water swarmed with myriads of a large Appendicularia floating backwards and forwards with the tide. The animals were extricating themselves from their "houses" and swimming free. The discarded "houses" continued to drift about for days, and were washed up on the beach in windrows.

# POLYZOA.

The study of the Polyzoa brought home by the expedition has been attended with great difficulty on account of the absence of identified material in the National Museum for comparison.

i have been able to make out three species, which were preserved in alcohol. They are as follows:

## CHILOSTOMATA.

#### 1. GEMELLARIA LORICATA (Lin.) Busk

Year.	Name.	Citations.
1758 1867 1875 1878 1878	Gemellaria loricata, Litken	Octv. af K. Vetensk-Akad. Förhandl., xxiv, p. 286, pl. xvii, fig. 54.

One large cluster was found washed up on the beach near the station.

It has been recorded from the Baltic, Norway, Spitzbergea, Greenland, England, the Gulf of Saint Lawrence, New England, Nova Zembla, and northwards towards Franz Josef Land during the drift of the Tegethoff.

## 2. FLUSTRA PAPYREA (Pall.) Smitt.

Year.	Name.	Citations.
1867 1875	Flostra pappiracco Lutken	Octv. af K. Vetensk-Akad. Förhandl., vxiv, p. 359, pl. xx, flgs. 9-11.

This species occurred in very great abundance off Point Franklin, in 132 fathoms,

and.

ch T droions.

moro dant

oast, ere a

vater

was close

tion. etroIt has been found on the eastern coast of North America north of Cape Cod, in Greenland, the Mediterranean (*teste* Smitt), and the Atlantic from the British islands to Spitzbergen and Nova Zembla.

#### 3. LEIESCHARA SUBGRACILIS (D'Orb.) Smitt.

Yea	. Name.	Citations,		
! 178 1 186	Muriozogu suberacile, Packard	Can. Natur. & Geol., viii, p. 411, pl. ii, fig. 5.		
186	Myriozona subgracile, Littken	Octv. af K. Vetensk Akad. Förhandl., xxiv. Bihang, p. 18. (Nominal list). Ateric Manual, p. 140. Denkschr. d. K. Akad. d. Wiss., xxxv. p. 289.	İ	
187 187 188	Leieschara subgracilis, Smitt	Octy, of K. Vetensk, Akad, Förhandl, xxxy, No. 3, p. 20, Vega-Exp. Vetensk, lakt., i, pp. 697-706 (passim).	1	

This was very abundant off Point Franklin. It has been previously obtained in Labrador, (Packard), Greenland (Fabricius and Lütken), Spitzbergen, and Nova Zembla (Swedish expeditions), and north of Nova Zembla towards Franz Josef Land (Austro-Hungarian Expedition).

Membranipora sp. and Discopera? sp. were found incrusting the dead gastropod shells that washed up on the beach.

At least two other other species of Polyzoa, which at present cannot be determined, were dredged off Point Franklin.

## PORIFERA.

At least three large species of sponges, one (probably) keratose and two (or three !) silicious were dredged off Point Franklin.

They were all obtained in considerable abundance, and are in a good state of preservation, but are quite indeterminable with the resources at my command. They will have to be reserved for future special study.

#### SUMMARY OF POLYZOA

3 Dragged up on coddings

in the foregoing report I have endeavored to make the synonymy of the species as complete as possible for references to works on arctic and boreal zoology, and have generally confined myself to such references.

The following list does not undertake to be a complete bibliography of the subject, but contains the most important works, chiefly on arctic or boreal zoology, which I have been able to examine myself. They are arranged charpologically.

## LIST OF WORKS CONSULTED IN THE PREPARATION OF THIS REPORT.

- 1774, PATLAS, P. S. Petri S. Pallus, M. D. Profess, Hist, Nat. et Acad. Scient, Imper, Petropol, membr, ordin. Acad. C.es. Nat. Cur. et Soc. Reg. Anglic. Sodalis Spicilegia Zoölogica Tomus I, continens Quadrupedium, Avinn. Amphibiorum, Piscium, Tasectorum, Molluscorum, Alicrumque marinorum fasciculos decem. 2 vols. 460. Berlin.
- 1774. PHPPS, CONSTANTINE JOHN. A Voyage towards the North Pole undertaken by his Majesty's command. 1773.

  By Constantine John Phinos, London.
- 1776. MULLUR, O. F. Zoölogiæ Danicæ Prodromus, seu Animalium Daniæ et Norwegiæ indigenarum characteres, nomina et synonyma imprimis popularium. Anctore Othone Friderico Müller, Regi Daniæ a Consiliis Status, Acad. 8 ient. N. Curios. Holmens, et Boicæ, Havniens, Norv. Berolinens, aliarumque Societ. Liter. Sodali, Acad. Paris Corresp. Copenhagen.
- 1780. Pamacu s, Ottio. Tanna Gredlandica, systematice sistems Animalia Grenlandia occidentalis hacternis indigenta, epocal norte in specificine, triviale, vernaculumque; synonyma anctorum plurinoc, descriptionem, locum, vectare, je metatrocem, mores, usum; capturamque singuli, prout detegendi occasio fuir maximaque postis secundum programs observationes Othonis Fabricii ministri evangelii, quondam Graciandis ad coloniam Friderichshrab, posthac norvagis 1 rangedallic, mue vero Danis Hopunti Intiae, membri societate scientiarum quae est Hafance, pp. xvi. 152, pl. 1. ## VI.-REPORT ON THE MOLLUSKS.

By W. H. DALL.

Opportunities for collecting mollusks are not very good at this northernmost point of the United States. The shores are covered with snow during a large part of the year, and the waters with ice. The latter is frequently grounded and driven upon the beach or over the shoal water adjacent to the beach, so that mollusks must find it a rather disagreeable station to inh, bit, provided they can secure themselves against freezing or crushing. There are no fresh-year stells, though it is probable that a few species occur at a not very great distance inland. The shape is composed of sand and gravel, which is constantly undergoing minor changes. There are few reaweeds, and the phytophagous littoral mollusks, so abundant at most stations more to vorably situated, are altogether absent. There are some places along this stretch of coast where arong currents meet and ice seldom grounds; where eddies permit the deposition of a moderate amount of mud and occasional small seawceds manage to exist, anchored on little pebbles or ridic 2 on the backs of crabs. In such places mollusks abound, individuals, if not species, being numchast. One such locality is well known as a good dredging ground, namely the vicinity of the Seahorse Islands or Cape Franklin, from a couple of hauls near which the best part of the present collection was obtained. A few additions were made to the list in Norton Sound, Unalashka Harbor, &c., but the opportunities for dredging or surface-collecting were not abundant. Considering the disadvantageous circumstances, the naturalists of the party must be commended for their energy and success.

#### SPECIES COLLECTED.

### CEPHALOPODA.

Octopus grænlandicus (Dew.) Mörch.

A fine specimen on the beach near the station. This has been examined by Professor Verrill, who agrees with the writer as to its distinctness from the *O. punctatus* Gabb, so common further south. Museum number, 40953.

#### PTEROPODA.

Limacina Pacifica Dall.

On the surface of the water off the station in July, 1882. Collectors' number, 650; museum number, 40954. This pretty species, which is very much larger than the Atlantic form, was originally described from the North Pacific.

#### GASTROPODA.

## PULMONATA.

Cochlicopa lubrica Müller.

Cionella subcylindrica Lehnert, Science Record, vol. ii, No. 8, p. 172, Boston, June 16, 1881.

Two specimens in moss from the tundra near Uglaämi.

Zonites (Conulus) Stearnsii Bland.

Hyalina arctica Lehnert, J. c., p. 172.

Ten or twelve specimens from the tundra moss. This has been erroneously referred to the genus or section *Microphysa*.

H. Ex. 44--23

177

Zor ves. Hvalina radiatula Alder.

Hyalion pethacida Lehnert, L. C.

Three or four specimens with the preceding.

The above were obtained from moss used in packing and rejected as rubbish, which was examined by the Rev. E. Lehnett, of Washington, who published in Science Record an interesting list of plants obtained from it, together with a spider, a minute beetle, and the above-mentioned shells By the kindness of Mr. Lehnert they have been carefully compared with authoritative specimens, and he joins in the identification above made.

Bela (exarata Woller).

This specimen is too dead and worn to be determined with certainty. It was obtained by dredging 10 miles west from Point Frauklin August 31, 1883, in 131 fathoms. Museum number, 10955.

Bela - scalaris Meilet . .

This specimen was in much the same state as the preceding. It was dredged in Norton Sound in 5 fathous mad. Museum number, 40956,

Belt simplex Vidos donn

Legal at A. Adames

Research Verkruser

One dead but perfect specimen from 5 fathoms mud and sand at Cape Smythe. This species has been confounded with B, larginata Dall, which is about one-eighth as large when adult, and altegether different in color and form. B. larigata has hitherto only been found in Norton Sound, where it is abundant. B. simplex has not yet been found in Norton Sound, but has a wide distribution in the boreal and Arctic region, reaching as far south as Chirikoff Island in the North Pacific, It has been obtained on the northern shores of Norway, and is not rare in Bering Sea. The present specimen is uni-colored, but it is usually prettily contrasted with white on the spire and plum-color anteriorly. Museum number, 10957,

Bela tenuilirata Pa-

Bela var, tenado ata, Dall, Am, Jonen, Conch., vii, p. 98, November, 1871 B. simplex, G. O. Sars, Moll. Reg. Arct. Nov., t. 17, f. 4, 1878, not of Middendorff.

This species, distinguished from the preceding by its spiral striae and thinner shell, was originally described from a young specimen obtained in Norton Sound. Since then the writer has obtained it of much larger size from the Arctic, reaching nearly an inch in length. It was collected by Murdoch on the beach near the station, and also at Cape Smythe in 5 fathoms. Museum number, 40958,

Bela harpa De

[17] J. J. Dall, Proc. U. S. Nat. Mus. 1884, p. 523.

Shell fusiform, moderately thin, six-whorled; whorls rounded, suture distinct; sculpture consisting of (on the last whorl) 23 stout, uniform, slightly flexuous, rounded ribs, extending from the suture to the canal, with slightly narrower interspaces; lines of increase distinct, sometimes threadlike: these are crossed by numerous close-set spiral threads separated by narrower grooves, both faint near the suture: threads growing gradually stronger, regularly wider, and coarser toward the canal, near which they are stronger than the obsolete ends of the transverse ribs; anal fasciole indisfinet, aperture narrow, clongated, with an acute posterior angle: outer lip thin, columella simple, canal rather wide; color of shell whitish, with a reddish tinge anteriorly, especially on the last whorl; interior of aperture reddish, of the canal pure white. Longitude of shell 17, of last whorl 12,5, of aperture, 10; latitude of shell 8, of aperture 3,5mm. First found by the writer at Nunivak Island in 1874. One specimen, diedged by the Point Barrow Expedition in 13½ fathoms, 10 miles west of Point Franklin, Arctic Ocean, Museum number, 10959,

This species has been compared with the Belas in the chief museum and private collections of Northern Europe, and seems amply distinct from any of the species contained in them.

Bela murdochiana Dall.

Rela murdochiana Dall, I. c., p., 524, plate 2, fig. 8.

Shell whitish, stout, short, with rather coarse sculpture and very short spire; whorls about five, last much the largest; inflated, suture deep, almost channeled; sculpture of numerous (on the last whorl about two to the millimeter) narrow, backwardly convex, flexuous riblets, with about equal interspaces, strongest near the suture, not crossing the fasciole, and obsolete near the periphery; lines of growth distinct, crossed by numerous (about six to the millimeter) rather coarse threads, of which each alternate one tends to be smaller, separated by narrow grooves, and about uniformly distributed over the

surface, with a tendency to a faint carina in front of the fasciole; fasciole indistinct, outer lip sharp, columella simple, white; aperture pinkish, canal short, wide; nuclear whorls eroded in the specimens; operculum light born color, rather broad and short; soft parts pink. Longitude of shell 11.5, of last whore 10; maximum latitude of shell 8.5 mm. Museum number, 40060.

Specimens from Cape Smythe in 2 to 5 fathoms mud and sand, with young B. tenuilirata, from which they differ in lighter color of shell, coarser sculpture, and stouter proportions. The operculum of B. tenuilirata is almost black, narrow, and claw-shaped. It is dedicated to Mr. Murdoch, naturalist of the Point Barrow party.

Admete Middendorffiana Dall.

Admete vividula Midd, Mal. Ross., ii, pl. ix, figs. 13-14, 1-49; not of Tabricius.

This form is perfectly distinct from A. riridula, and may prove to be a Cancellaria. It is one of the characteristic forms of the Pacific Arctic, and ranges north from Nunivak Island. The present specimen was obtained in Norton Sound in 5 fathoms mad. Museum number, 40961.

Buccinum tenue Gray.

Beach near the station; also at the dredging spot 10 miles west of Point Franklin in 13½ fathoms. Museum number, 40962.

The specimens from the last station included some in which the characteristic broken ribbing was only represented by a few puckerings near the suture, the remainder of the shell being inflated and smooth, except for the fine spiral striation. At first sight these were very puzzling, and might readily have been taken as new without careful study.

Buccinum Baeri Middendorff,

One specimen from 10 miles off Point Franklin in  $13\frac{1}{2}$  fathoms, dead, and inhabited by a Pagarus. This is a very constant form, but probably only an extreme form of B. cyencum. Museum number, 40963.

Buccinum ciliatum l'abricius.

One dead and two living specimens from 10 miles west from Point Franklin in 13½ fathoms. Museum number, 40964. This is always a very recognizable species, but rare in individuals. It extends in Bering Sea, south to Nunivak Island.

Buccinum glaciale Linné. Plate -, figs. 7-5.

Beach near station; also with Pagari in various dredgings. Museum number, 40965. Common to the whole of the Arctic basin north of St. Laurence Island, as well as on the Atlantic side. Further south it assumes other forms, some of which, without the connecting links, appear very distinct, and have been described as species by Mörch and others. The strictly Arctic varieties are B. carinatum Phipps, and a form which in its coarser features so closely simulates B, angulosum var. angulosum Gray that it has been taken for it, and the consolidation with B, glaciale of B, angulosum suggested in consequence. The fine sculpture in perfect specimens will always serve to distinguish them. Normal specimens would never be confounded with each other.

Buccinum angulosum Gray. Plate --, figs. 1-4.

- A. Var. angulosum Gray, Beechey's Voyage. Zoöl., p. 127, t. 36, f, 6, 1828.
- B. Var. normalis Dall.
- C. Var. subcostata Dall.

The normal form was obtained by the expedition on the beaches near the station and at Capo Smythe: thence to 5 fathoms. Museum numbers, 40966-7. The writer has also obtained it at

Sound

s origier has Hected useum

e conim the hreadi, both rd the indisimple, vhort; 2.5, of Island s west

ons of

numerous points in this part of the Arctic basin. The angulated form is less common, and every grade exists between them. The fine sculpture, and especially the sharp transverse striae, always distinguish it from other species, especially the angulated varieties of glaciale.

Buccinum plectrum Stimpson. Plate III, figs. 9, 10.

Beaches near the station. Museum number, 40968. The variety collected by the expedition is a rather dwarfed form, with intensified sculpture. The metropolis of the species is further south, and I have seen fine specimens from the Shumagins. This is an excellent species and easily distinguished when in good order. It has been mistaken for a variety of *B. undatum*, which is not found in any shape on the Pacific side. A few fraudulent specimens were sent out as from this region by a recently deceased conchologist, but they bore all the marks of having come from London dealers. It is possible that the whalers, who carry and mix shells from all parts of the world, may have been the unintentional means of having distributed a few specimens with erroneous locality labels.

Buccinum polare Gray. Plate III, figs. 5, 6.

Beaches near station; also dredged in 13½ fathoms off Point Franklin. Museum numbers, 40969-70.

This species, which is also well characterized, varies from inflated, large, with fine, sharp carine to small, elongated, with obsolete carine, and is sometimes rather puzzling; but a good series makes the relations clear. It is frequently of a bright, clear orange color, and is generally quite thin. I have seen two specimens of a singularly thick and short variety percrassum from the Arctic north of Bering Strait. It must be exceedingly rare; the upper whorls are smaller, less inflated and less turreted than in the normal form. The operculum is also proportionally larger and more oval. It may prove distinct from polare.

Chrysodomus Kroyeri Möller.

C. Kroyeri, var. Rayana Dall, 1, c., p. 525.

One small one in the state called *cretaceum* by Reeve, at Cape Smythe, on the beach; a very large living specimen of the normal form, in 5 fathoms, from the same locality, some with few ribs from 2½ fathoms at the same place. Museum numbers, 40971–2. This shell, when fresh and perfect, is of a plun color or dull purple, with fine, spiral striæ, recalling *B. tenue*, and strong transverse ribs. When dead and weathered, it turns nearly white—this is Reeve's form; an extraordinary variety *Rayana* has no ribs but is perfectly smooth, except for the fine sculpture which enables its true relations to be determined. This last, named in honor of Lieut. P. H. Ray, United States Army, who commanded the Point Barrow expedition, would be taken as distinct at first sight. The specimens were all rather young, which made their recognition still more difficult. It was also dredged at Cape Smythe.

Chrysodomus liratus Martyn.

C. tornatus Gould.

One specimen from the beach near the station. Museum number, 40973. The metropolis of this species is much further south.

Chrysodomus fornicatus (Gmel.) Gray.

Rare on the beach near the station; abundant near the Mackenzie River mouth, and at Numivak Island, with innumerable varieties. Museum number, 40974.

Chrysodomus spitzbergensis Reeve.

C. terebralis Gould.

One young living specimen, Norton Sound, in 5 fathoms. Museum number, 40975.

Chrysodomus martensi Krause.

One specimen on beach near station. Museum number, 40976. This species was obtained by the writer in Bering Strait in 1880, in 30 fathoms; subsequently by Dr. A. Krause in the same region, in whose report it is about to be described.

Heliotropis harpa (Mörch) Dall.

Finus deforme Midd. Mal. Ross, ii, p. 140, 1840, not of Reeve.

One young, living specimen in 13½ fathoms, 10 miles west of Point Franklin. Museum number 40977. This species is distinguished from F. deforme by its coarser spiral strice and brighter colors. It extends south to the Aleutians, where it reaches a very large size. The undefined name Pyrulofusus was applied to the Atlantic species by Mörch.

Strombella Beringii (Midd.) Dall.

Tritonium Bertugli Midd, Mal. Ross, ii, p. 147, pl. 3, figs. 5-6, 1849.

A dead specimen on the beach near the station. Museum number, 40978.

The genus Strombella Gray is slightly anterior to Volutopsis of Mörch, and has the advantage of a diagnosis. The Strombella of Schleuter, which has been unnecessarily assumed to exclude Gray's name, has no standing whatever, being a mere word in a catalogue without diagnosis or identified type or description of any kind.

This species has fewer transverse ribs than Chrysodomus Kennicottii Dall, with which it has been confounded, and wants the fine characteristic sculpture of the latter. From the following species it differs in its light color; rude, short spire, absence of carine, more rapidly increasing whorls, rounded concavities between more numerous (ibs., and few coarse spine or threads.)

Strombella malleata Dall.

Strombella malleata Dall, 1, c., p. 525,

One specimen from the beach near the station. Museum number, 40979. The writer has collected this species at Icy Cape, Cape Lisburne, Point Lay, Kotzebne Sound, Point Spencer, at Port Clarence, and other localities within the Arctic basin.

It is long and slender, the young shell forming several whorls in an almost cylindrical coil before they begin to enlarge; the adult may reach six inches in length. The surface is covered with tine spiral strice and a thin brown epidermis. It differs from the preceding in its dark purple color, its few (generally five) transverse ribs, between which the space is nearly flat rather than concave, and a sharp carina on the anterior periphery of the last whorl on which the suture is laid. The nucleus is large and blunt, the canal short, the form of the mouth variable in different stages and specimens; the outer lip thin, the aperture dark purple within the last whorl, less than half the length of the shell in nearly all cases. It is usually rude and more or less worn, even when living; the cylindrical tip is usually broken off, but the polygonal section of the whorl is very characteristic.

Trophon clathratus I.,

A dead specimen at Cape Smythe, and another, rather stouter, at 10 miles west from Point Franklin, in 13 $\frac{1}{2}$  fathoms, mud and sand. Museum number, 40980. This species is very variable in relative proportions and closeness of varices.

Turritella (Tachyrhynchus) polaris Beck.

T. crosa Conthony.

One specimen, ten miles west of Point Franklin, in 133 fathoms mud. Museum number, 40981.

Trichotropis borealis Broderip & Sowerle

One specimen in 5 fathoms; Norton Sound; dead. Museum number, 40982.

Trichotropis (Iphinoë) arctica (Midd.) Dall.

Cancellaria arctica Midd. Mal. Ross, ii, p. 112, pl. ix, figs. 41, 12, 15, 4849.

Beach near station, also Norton Sound, in 5 fathoms. Museum number, 40933. It was originally brought by Wossnessenski from Bering Strait.

Crepidula grandis Middendorff.

One young specimen from 13½ fathoms, 10 miles west from Point Franklin. Museum number, 40984.

al hy same Natica clausa Broderio & Sowerby.

Common on the beach near the station; also at Cape Smythe, 2½ to 5 fathoms; also off Point Franklin in 13½ fathoms. Museum numbers, 40985-6. The specimens have the fine brown color which seems characteristic of those from more northern stations; a few show the white basal area characteristic of X, russa, but do not otherwise approach that species; all are of moderate size and rather thin.

The identification of Gmelin's affinis with this species does not seem sufficiently certain to render its adoption in place of clausa desirable.

Lunatia pallida Broderip & Sowerby,

Abundant in the same localities as the preceding. Museum numbers, 40987-8.

Lunatia Bulbus flavus Gould.

Natica flava Gould, Sill, Journ., xxxviii, p. 196, Rep. Inv. Mass., p. 239, tig. 162, 1842.

A few fine dark brown specimens from the beach near the station. Museum number, 40989. This clegant species is quite distinct from the Natica (Bulbus) Smithii of the north of Europe.

Lunatia Mamma nana Möller.

One specimen from Norton Sound in 5 fathoms. Museum number, 40990.

Amauropsis purpurea Dall.

A. helicides Middendorff, not Johnstone.

With N. clausa, but less common. Museum number, 40991.

Velutina coriacea (Fall, ) Middendorfi.

One specimen on beach near the station. Museum number, 40992.

Scala groenlandica Chemnitz.

One specimen with the preceding. Museum number, 10993.

Margarita striata Brod, & Sow.

One or two specimens from the beach near the station. Museum number, 40994.

Margarita vorticifera Dall.

One specimen with the preceding. Museum number, 40995.

This is much further north than the species was previously known to range.

Margarita obscura Cogthony.

Several specimens from 5 fathoms mud in Norton Sound. Museum number, 40996,

Patella Helcioniscus exarata Reeve.

A single specimen of this well-known Hawaiian species was collected dead on the brach. If was andoubtedly thrown overboard with ballast from some whaler which had refitted at Honolulu, and is interesting as showing an accident of distribution, like Mr. Lord's living Orthalicus undatus from Vancouver Island. Museum number, 10997.

Amicula vestita (Sby.) Dab.

- Chitan Functsonii Conthoux,

Abundant 10 miles west of Point Franklin in 133 fathons. Museum number, 1099s.

Cylichna alba Promin.

A few specimens from 5 fathours mud and sand off Cape Smythe. Museum number, 40999, Cylichna prepinqua M. Sars.

Rether abundant in 2½ to 5 fathous off Cape Smythe. Museum numbers, 41000-41001.

? Dendronotus Dalli Bergh

One specimen of a species of *Dendronotus* was taken in the act of spawning, off Cape Smythe, in 5 fathous, August 14. As the above species is the only one described from north of Bering Strait it is probable that it should be so identified. Museum number, 41002,

Acolidia papillosa (Linné) Bergh.

With the last, and also crawling on the stones, at low-water near the station. Museum number, 41003,

Note.—This completes the list of gastropods, but it may be mentioned that a specimen of *Pricae oregonense* Redf. was brought by the expedition from Unalashka, but, belonging to a different fauna, it has not been formally included in the list.

#### ACEPHALA.

Mya truncata Linné.

Living on the beach near the station of Uglaami. Museum number, 41004.

Macoma sabulosa Spengler.

Beach near the station and at Cape Smythe in 23 to 5 fathoms. Museum number, 41005,

Liocyma fluctuosa (Gld.) Dall.

Cape Smythe,  $2\frac{1}{2}$  to 5 fathoms; also 10 miles west of Point F wiklin, in  $13\frac{1}{2}$  fathoms mud and sand. Museum number, 41006.

Cardium (Serripes) grænlandicum Chemnitz.

Living near low-water mark to  $2\frac{1}{2}$  fathoms at the station; also Norton Sound at 5 fathoms, and at Cane Smythe in  $2\frac{1}{2}$  to 5 fathoms. Collector's numbers, 195 and 1761. Museum numbers, 41007-8.

Cardinm islandicum timelin.

Norton Sound, in 5 fathoms mud. Museum number, 41009.

Cryptodon sericatus Carpenter.

At Cape Smythe in 5 fathoms; also off Point Franklin in 13½ fathoms, mud and sand. Museum number, 41010.

Astarte (Rictocyma) Esquimalti (Baird) Dall.

Crassatella Esquimalti Baird. Rictocyma mirabilis Dall (young).

Two specimens, 10 miles off Point Franklin, in 13½ fathoms. Museum number, 41011.

Astarte fabula Reeve

Norton Sound in 5 fathoms. Museum number, 41012.

Veneticardia borealis Conrad.

One specimen of the variety V. novangliw Morse was found on the beach near the station. Museum number, 41013,

Yoldia limatula Say.

One specimen from 15 fathoms, mud, off Point Barrow. Museum number, 41014.

Yoldia myalis Conthony.

Off Cape Smythe in 23 to 5 fathoms. Museum number, 41015,

Yoldia lanceolata Sowerby

With the last. Museum number, 41015a.

Pecten islandicus Omelen.

Living, off Point Franklin in 13½ fathoms; dead, on the beach near the station. The color of these northern specimens is apt to be of a peculiarly deep rich tint of red in various shades. The living specimen carried on its upper valve a fine specimen of *Chelysoma macleaganum*, an *Actinia*, numerous Sertularian hydroids, and several species of *Polyzoa*. Museum number, 11016.

#### BRACIHOPODA.

It is apparent from this list\* that four families greatly preponderate, namely the *Pleurotomida*, *Buccinida*, *Naticida*, and *Trochida*, as represented by *Margarita*. While the party doubtless obtained a full representation of species resident at or near the station itself, it should be added that the mollusk fanna of the Arctic basin adjacent is considerably larger than the number of species included in the preceding list. There is practically but one fauna from Nunivak Island nerthward to the Polar region, though there are a number of species which do not occupy the whole area, especially littoral forms.

The writer has been gathering material for twenty years toward a faunal description of this region and hopes before long to be able to prepare it for publication, a task which, from the pressure of other duties, has hitherto been unavoidably deferred.

Towards such a complete description such contributions as this, made by the party under the command of Lieut. P. H. Ray, are particularly valuable, and to Mr. Murdoch and his companions, who went into practical exile for two years for the benefit of science, the sincere recognition and hearty thanks of all naturalists are unquestionably due.

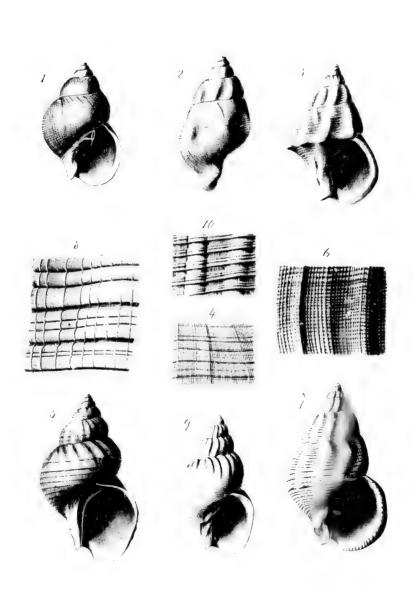

<sup>5</sup> In the list, species obtained at Cape Smythe, Point Barrow, and near the station Uglaami, all within a rhort distance of one another, are included under the heading "Point Barrow,"

idæ, tless ided er of land the this ressthe ions, and chort

# VII.—COLLECTING LOCALITIES AND DREDGING STATIONS.

By John Murdoch, A. M., Sergeant Signal Corps, United States Army.

#### 4. BEACH, CAPE SMYTHE.

This locality comprises the steep pebbly beach and the inlets of the lagoons from about a mile and a half above the station of Ooglaamie to about 3 miles below it.

This stretch of shore was pretty thoroughly patrolled nearly every day during the season of open water. The daily tide is so small that few animals were washed up by its means, and the occasional periods of low water, caused by long-continued off-shore winds, exposed no shore-dwelling animals. The sea was never low enough to uncover the mud flats which are close to the shore. Most of the animals obtained on the beach were washed up whenever there happened to be a strong breeze and heavy sea on-shore.

Soon after we landed in 1881 there occurred several heavy gales from the west and northwest, and, as the ice-pack was a remarkable distance from the land, an exceedingly beavy sea rolled in upon the beach, bringing vast quantities of material. We were unfortunately so busy providing ourselves with shelter against the rapidly approaching winter that we were unable to preserve any specimens, and so favorable an opportunity never recurred.

Most of the material showed signs of having been transported a considerable distance. The lamellibranch shells especially were crushed and ground into small fragments.

The following species were obtained at this locality:

#### CRUSTACEA.

1. Hyas latifrons. 9. Hoperia medusarum. 2. Eupagurus trigonocheirus. 10. Themisto libellula. 3. Cheraphilus boreas. 11. Eurytenes gryllus. 4. Nectoerangen lar. 12. Onisimus littoralis. 5. Hippolyte gaimardii. 13. Eusirus cuspidatus. 6. ? Diastylis rathkii var. 14. Melita formosa, 7. Chiridotea entomon. 15. Gammaracanthus loricatus. 8. Chiridotea sabinci. 16. Peltogaster paguri.

## VERMES.

Melanis lovéni var. gigantea.
 Echiurus vulgaris.
 Arenicola glacialis.

#### ECHNODERMATA.

20. ! Trochostoma boreale. 23. Cro.saster papposus. 21. Strongylocentrotus dröbachiensis. 24. Solaster endecea. 22. Asterias acerrata.

POPELTIRA.

69. One or two species of sponges, undetermined.

## 2. SHOAL WATER ALONG SHORE, PERGNIAK, ELSON BAY.

The large fish-seine was hauled three times from the shore, in the southwest bend of Elsen Bay, close to the Eskimo summer camp of Pergniak, August 11, 1883. A few small whitefish and sculpins were caught, and the lead-line of the seine brought up a quantity of seaweed containing many amphipods of the following two species:

Gummarus locusta.

Gammaracanthus lorientus.

## 3. OFF CAPE SMYTHE.

Opportunities for dredging near the station were seldom offered on account of ice and bad weather. Most of the work was confined to a small area extending about a mile above and below the station, and from a depth of about 2½ fathoms, close to the shore, to 12 fathoms about a mile from the land. The bottom for the most part was an exceedingly tenacious and fetid black mud containing very little life except Worms and the large Isopods Chiridotea entomon and subinei. Interspersed with this, however, were occasional patches of sand and mud mixed, which contained more life. During the season of open water these patches were generally pretty well indicated by the flocks of ducks swimming over them, attracted by the comparatively rich food.

Dredgings were obtained August 14, 1882, and August 7 and 9, 1883. On August 8, 1883, an opportunity occurred to dredge in 15 fathoms, about three miles above the station and about two miles from shore, just outside the barrier of grounded ice. Two hauls of the dredge were obtained

with great difficulty as the current was too feeble to make our whaleboat drug the dredge. One had was made by making the boat fast to a large cake of floating ice. The bottom was the same black mad and contained animals similar to those obtained at the inshore stations.

The following species were obtained in this locality:

#### PACNOGONIDA.

1. Nymphon longitarse,

## CRUSTACEA.

18. Iphinoe arctica.

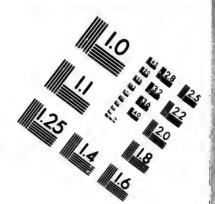

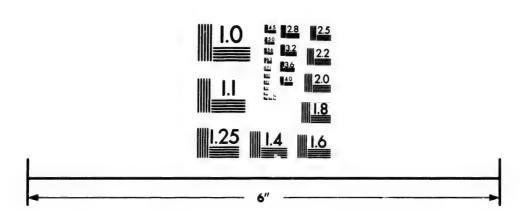

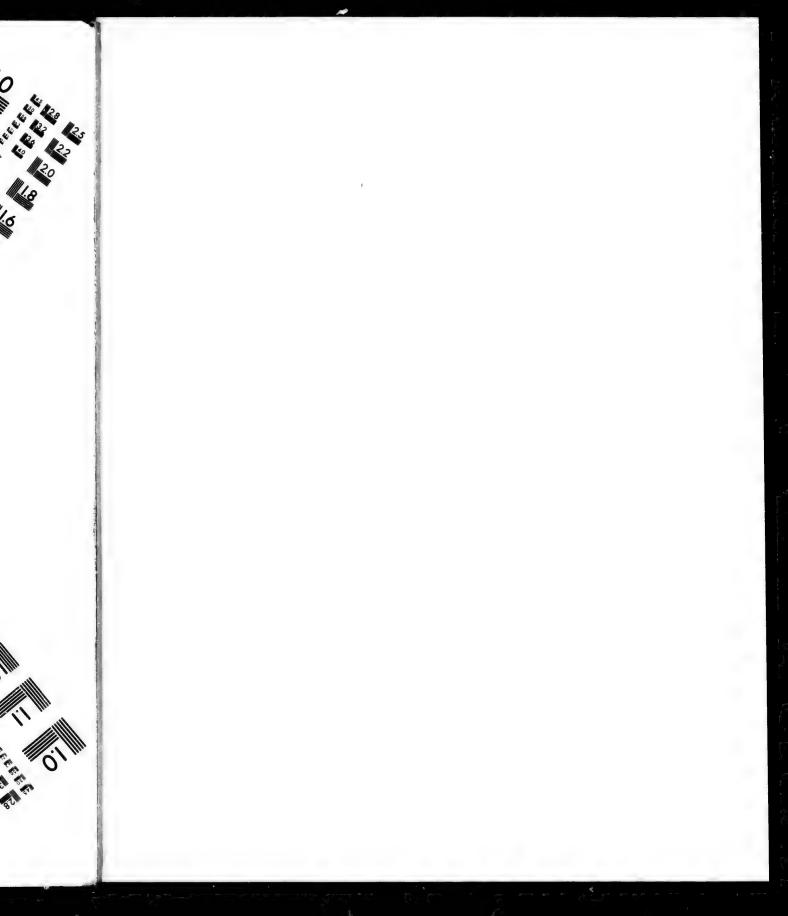

IMAGE EVALUATION TEST TARGET (MT-3)

Photographic Sciences Corporation

23 WEST MAIN STREET WEBSTER, N.Y. 14580 (716) 872-4503

It will be seen from the above lists that the region immediately about Point Barrow (Stations 1, 2, and 3) though comparatively poor in individuals, is quite rich in number of species, at least 115 having been collected. Of these the most abundant are Mollusks (41 species exclusive of land shells), Crustacea (22 species, not counting fresh-water forms), and Worms (19 species).

At Point Franklin (Station 4), on the other hand, although fewer species were obtained (62 in all) the number of individuals was simply enormous. The Mollusks were most numerous in species (21 species) but comparatively few in individuals. Crustacca were plentiful, both species and individuals. The Echinoderms were most abundant in individuals, though only 11 species were obtained. Great quantities of the two species of Polyozoa also were collected.

At Stations 5 and 6 animal life was poor both in species and individuals, though 12 species of Mollusks were obtained at Station 6.

## VIII.-PLANTS.

By Prof. Asa Gray, Cambridge, Mass.

This collection probably comprises most of the Phanerogamous plants growing at that Arctic station; some of them not before received by us from that region, rich as our herbarium is in Arctic American plants.

One of these is Ranunculus Pallasii, a most peculiar white-flowered species, which we now for the first time possess in copious specimens. With it comes a very depauperate R. multifidus, R. pygmæus and R. nivalis, and a radicant form of Caltha palustris, with leaves hardly a half inch long at flowering-time.

Paparer nudicante appears to be the most abundant, and perhaps the most showy, plant of that Arctic flora.

Parrya nudicautis is not in the collection, but Miss Heppingstone found it on Cape Lisburne. The other Crucifera are Cochlearia officinalis, or some other of the ill-defined species, Draba alpina, and some related white-flowered species which are not determined for want of fruit.

Stellaria longipes, var. Edwardsii. S. humifusa, and a condensed form of Cerastium alpinum are the only Caryophyllacea, and Astragalus alpinus and A. frigidus are the only Leguminosa.

The Rosacce are Dryas actopetala, var. integrifolia, and Potentilla emarginata Pursh., the latter in numerous and fine specimens. A very dwarf form of this species from Wrangel Island was inadvertently named P. frigida in the list of Muir's collection.

The Naxifrage are N. oppositifolia, N. hirculus, N. flagellaris, N. sileniflora, N. hieracifolia, N. punctata, in a most reduced form, with some stems only a span high, a compact inflorescence, and small leaves which are crenately 7-9-lobed rather than dentate, which is here called var. nana, also S. stellaris, var. convexa, N. rivularis, var. hyperborea, and N. cernua.

Valeriana capitata of Pallas was sparingly collected.

Stations at least of land d (62 in species ad indi-

ecies of

The Composita are only three, Petasites frigida, Senecio frigidus, and Arctie forms of Taraxacum officinale, var. lividum.

The Ericacea are even fewer, being only Vaccinium ritis-ida and Cassiope tetragona.

The remaining Gamopetalw are only Mertensia maritima in a condensed form, Pedicularis Sudetica, and P. Langsdorfli.

The Apetale, Polygonum viviparum, Oxyria digyna, Rumex salicifolius, and the following willows, which have been examined and named by Mr. Bebb. An abstract of his notes upon them is here given:

Salix oralifolia, Trauty., in both sexes, and with well-formed fruit. Clearly an Arctic modification of S. myrtilloides, with subsessile capsules.

Satix glacialis, Anderss., with female flowers, and young foliage, agreeing with the character in the want of a style.

Salix buxifolia, Trev. (S. phlebophylla Anderss.), with nervose lineate leaves and a manifest style. Salix rotundifolia Trauty., which is probably only S. polaris with glabrous capsules.

Salix fulcrata Anderss., in both sexes. Distinguished from 8. chlorophylla mainly by its stipules, which in these specimens answer to Siemann's plant, but not to Andersson's figure.

No petaloideous Monocotyledon was collected except Luzula arenata; of Glumacca, only Exiophorum Chamissonis and an immature Carex, which may be C. rulgaris; and of grasses a fine stock of Phippsia algida, Arctagrostis (Colpodium) latifolia, Alopecurus alpinus, Graphephorum (Dupontia) Fischeri; and G. fulvum, Poa benisia, and P. arctica, also a true Colpodium, the species undetermined.

Dr. Farlow adds the following report upon the Lower Cryptogamia of the Point Barrow col.

lections:

I would make the following report on the cryptogams collected at Point Barrow and submitted to me for examination. The lichens consisted of three packages, each containing a single tuft of unpressed material. Two of the tufts were composed of Cetraria islandica Ach., var. Delisari Bor., and the third of Alectoria divergens (Ach.) Nyl., mixed with which were fragments of Cetraria arctica (Hook.) and Thannolia vermicularis (Sw.) Schaer. There was a quantity of fungi preserved in a jar of alcohol, but without notes of color, habit, &c., so that the specific determination is in their present condition impossible. The specimens, as far as could be told, seemed to include two species of Agaricus and one of Russula.

The Algae collected were in part marine and in part from fresh water, some of them roughdried, and others prepared on mica.

The marine species were as follows:

Phyllophora interrupta (Grev.) J. Ag., in excellent condition, with fully-developed nemathecia; Odonthalia dentata Lyngb., rather a broad form, with slender supra-axillary tetrasporie branchlets; fragments of a sterile species which possibly belonged to Rhodymenia pertusa (Bail, and Harv.) J. Ag.; and fragments of an Ulva which could not be determined.

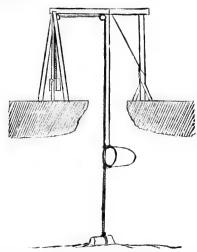

The fresh-water species included several specimens of a *Prasiola*, which may be referred with some doubt to *P. crispa* (Lightf.) Kg. The specimens were considerably larger than the type, some being nearly three inches long, but the habit was prostrate and bullate, and there was no distinct stipe as in *P. stipitata* Suhr., a species previously reported from the Arctic regions of America. It is possible that the species may prove to be new, but, as the specimens agree in microscopic structure with *P. crispa*, it would not be well without further information to separate them as a distinct species. Besides the *Prasiola* mentioned, the material on mica contained *Pediastrum Boryanum* Menegh, and two *Cyanophycea*, *Aphanothece stagnina* A. Br., and *Aphanacapsa Castagna* (Breh.).

# APPENDIX.

By John Murdoch, A. M., Sergeant Signal Corps, United States Army.

# A.—NOTES ON SURFACE LIFE UNDER THE SEA-ICE, FROM FEBRUARY 27 TO JUNE 8, 1883.

At the suggestion of Lieutenant Ray, a towing-net was arranged so that it could be attached to the line of the tide-gauge and set at different depths under the ice (see diagram). The water was about 17 feet deep. When a strong current was running in either direction the net was distended and many animals captured.

The net was visited generally every day, unless the weather was too severe to handle it. Early in the season the bucket of water containing the washings of the net was so full of ice-crystals that it had to be thawed before the stove before it could be examined.

February 27.--Current NE. Temperature of the water, 29°.1 F., net set near the bottom.

Small copepods resembling Cyclops, a few.

. Egina citrea, 2 small ones.

Turris? sp., a few small.

February 28.-Conditions as above.

Copepods; rather plenty.

Diastylis sp., 1, small.

Beroë roscola, 1, about 0.2 inch long.

.Egina citrea, 1 or 2, very small.

March 4.—Current and temperature as before, net set near surface.

Diastylis sp., 1, small.

Copepods; a few.

Beroë roscola, very abundant, from size of pin-head to about 0.3 inch in diameter.

April 4.- Net loaded with ice-crystals.

April 5.—Current SW. Temperature of water 299.1 F. Water muddy. Net clear of ice. Life scanty.

Beroë roscola; a few; small.

Sarsia rosaria; a few.

April 7.—Conditions as above. Life very scanty.

April 10 .- Conditions as above: Water muddy. Life scanty.

Copepods; a few.

Beroë roscola; a few and small.

.Egina citrea; 2 or 3; very small.

Sarsia rosaria; 1, small.

April 11.-Conditions as above. Life scanty.

. Egina citrea: 2, small.

Sarsia rosaria; 2 or 3 (one larger than usual, about 0.4 inch).

April 12.—Current NE., almost slack. Water muddy. Life very scanty.

April 14.--Current slack. Water and net very muddy. Life very scanty.

April 16.—Current slack. Water and net less muddy. Practically no life.

Until April 24 the current continued slack, and no life was observed. On that date there was a slight SW, current, but practically no life.

April 26.—Current NE., rather strong. Temperature continued the same.

Beroë roscola : 1: small.

. Egina citrea; 1; medium-sized.

Sarsia rosaria; rather plenty.

April 27.--Current NE., slight. Water decidedly milky.

Copepods: a few.

Beroë roscola; a few; small.

Conditions unfavorable for tending the net until May 6.

May 6.-Slight NF, current. Temperature unchanged. Water muddy. Lafe scanty.

Copepods: 1 or 2.

Sarsia rosaria; rather numerous.

May 8 .- NE, current, rather strong. Water muddy.

? Clione borealis, larva; 1.

Sarsia rosaria; rather plenty; very small.

May 10 .- Moderate NE. current. Water muddy. No life.

May 11.—Current slack.

May 14.-Current SW. in morning, slack at night.

Nothing in net. (Found a large Beröii roseola 4 inches long in tide hole, dead and much dilapidated.)

May 15,-Weak NE. current. Water very clear. No life.

May 18 .- Strong NE. current. Water muddy. Life scanty.

Copepods: a few.

Beroë roscola: a few: small.

.Egina citrea; 1 or 2. Sarsia rosaria; a few.

May 19,-Strong NE, current.

? Clione borealis, larva; a good many; no further developed.

Beroë roscola; plenty; very small.

Sarxia rosaria; 1 or 2.

May 21.-Strong NE. current. Water muddy.

? Clione borealis, larva: a few.

Beroë roseola; 2; about 4 inch long.

Sarsia rosaria: 1.

May 22.-No current.

May 23.-Strong NE, current. Life scanty.

? Clione borealis, larva; a few.

A few very small acalephs.

May 24.—Strong NE, current.

? Clione borealis, larva: plenty (some have grown larger).

Berow roscola; very abundant, from very small to size of filbert. (Saw one very large one, 6 or 7 inches long, dead, and somewhat broken.)

Egina citrea ; 1; large.

Melicertum sp.; 1.

Sarsia rosaria: plenty and large (about .75 inch).

May 26 .- Strong NE, current.

? Clione borealis, larva; a few.

. Egina citrea: 2 good-sized ones.

Narsia rosaria : a few.

May 27.-Strong NE, current. Water muddy. Life scanty.

Beroë roscola : 1 or 2.

Sarsia rosaria: 1 or 2.

May 30.—Current slack.

? Clione borealis, larva: a few.

May 31.—Current slack

. Egina citrea; 1; large.

June 2.—Rather strong NE, current. Life scanty.

? Clione borealis, larva; a few.

June 5.-Current slack. No life.

June 7 .- Strong NE. current. Life scanty.

? Clione borcalis, larva; a few.

June 8.-Current NE. Life scanty.

? Clione borealis, larva; a few. Net taken up.

During the whole period in which the net was set the surface temperature of the water remained very nearly constant at 29°.4 F.

The foregoing notes are presented as the first continuous series of observations on surface life during winter in the Arctic regions.

The only reference to any observation of the kind that I have been able to find in any of the accounts of Arctic exploration will be found in Dr. Sutherland's "Journal of a Voyage in Baffin's Bay and Barrow Strait," vol. 1, pp. 440-441. On December 3, 1850, the sea-water in the firehole was observed to be luminous, especially when agitated by the tide-line. \*\* \* \* \* A minute acaleph was discovered which seemed to possess cilia. \* \* \* \* The shape was perfectly globular, except when in a state of motion, and then it was rudely pyramidal." This was probably the young Beroi' roscola which we found so abundant under the ice.

B.—NOTES ON SURFACE LIFE OBSERVED DURING THE VOYAGE FROM SAN FRANCISCO TO POINT BARROW. AND DURING THE SEASON OF OPEN WATER AT POINT BARROW.

#### PACIFIC OCEAN.

#### 1881.

July 19.—Latitude 37° 6′ N.; longitude 124° 33′ W. (at noon). Large numbers of Velella sp. floated past the vessel.

July 20.—Latitude 36° 51′ N.; longitude 126° 33′ W. Velella sp.; less plenty.

July 21.—Latitude 37° 09′ N.; longitude 128° 44′ W. A few Velella sp.

July 23.—Latitude 38° 11' N.; longitude 134° 17' W.

Large numbers of *Lepas* sp. floating in bunches. July 24.—Latitude 39° 10′ N.; longitude 134° 54′ W.

Lepas sp.; plenty. July 25.—Latitude 41° 17' N.; longitude 135° 46' W.

Lepas sp.; plenty. July 26.—Latitude 42° 44′ N.; longitude 136° 18′ W.

Lepas sp. in unusually large numbers. July 28.—Latitude 45° 18' N.; longitude 136° 45' W.

Water filled with the shells of dead Velellw, to some of which were attached a single large blue barnacle (? Lepus sp.); Lepus sp.) plenty.

July 29.—Latitude 45° 02' N.; longitude 139° 37' 45" W.

Large numbers of Velella sp. dead or dying. July 30.—Latitude 45° 30' N.; longitude 141° 40' W.

Dead or dying Velella sp.; still very plenty.

August 4.—Latitude 42° 29' N.; longitude, no observation.

Salpa herculea; saw several.

August 11.—Latitude 54° 15' N.: longitude 158° 58' W.

Temperature of water at noon 52°.2 F. Water full of Medusar.

! Mertensia ovum; saw one.

? Aurelia labiata; plenty and small.

? Cyanea postelsii ; plenty.

? Pelania sp

Staurophora mertensii; very plenty and large.

In crossing Bering Sea we had rough weather and observed no surface life. Aurelia Inbiata was observed in Plover Bay, Eastern Siberia.

### ARCTIC OCEAN.

August 31.—Latitude 69° 01′ N.; longitude 166° 25′ W. Temperature of water, 47° F. Cyanca postelsii; rather plenty.

- September 4.—Latitude 70° 21′ N.; longitude 165° 16′ W. (80 miles west of Icy Cape). Temperature of water, 43°.8 F.
  - Water full of Beroë roseola.
- September 5.—Latitude 70° 21' N.; longitude 163° 43' W. Temperature of water, 44°.5 F.
  - Water full of Acatephs; large and healthy.
  - Beroë roscola; plenty.
  - Mertensia ovum; 1.
  - Pleurobrachia rhododactyla; very plenty.
  - Aurelia labiata; plenty.
  - Cyanca postelsii; plenty.
  - Staurophora mertensii; plenty.
- Noticed a few Pteropods.

### STATION, OOGLAAMIE, CAPE SMYTHE,

- September 16 .- Water full of Cyanca postelsii of large size and varying color.
- October 13.-Chrysaora melanaster washed up on the beach.
- November 10.—Water at noon filled with large medusæ, Aurelia labiata and Cyanca postelsii.

  Temperature of water, 29° F.
- November 11.—At noon observed one small living Cyanea postelsii. Temperature of water, 3000 F.
- November 28.—Cyanca postelsii and Aurelia labiata observed through a crack in the ice. Sea closed.

#### 1882.

- January 17.—Cyanca postelsii of large size observed in the hole cut for taking the temperature of the sea-water, which was 280.7 F.
- February 6.—Cyanea postelsii of large size taken in the temperature-hole. Temperature of water, 29° F.
- April 29.—Three living and healthy specimens of Beroi roscola about two inches long were taken in the temperature-hole. Temperature of water, 29° F.
- July 18.—Sea open between shore and grounded ice. Temperature of water, 39° F.
- Water swarming with a small nauplius (Balanus sp.). Observed a few pteropods (Limacina pacifica).
  - Beroë roscola; very bundant; mostly small.
  - Pleurobrachia rhododactyla; very abundant, of all sizes.
  - Aglantha camtschatica; very plenty.
- July 19.—Temperature of water, 40°.2 F.
  - Limacina pacifica; more abundant.
  - Beroë roscola; very abandant; mostly small.
  - Pleurobrachia rhododactyla; very abundant, of all sizes.
  - Chrysaora melanaster; two or three on bottom.
  - Aglantha camtschatica; quite plenty.
- July 24.-Limacina pacifica; rather plenty. Observed only one or two acalephs.
- July 31.—Temperature of water, 49° F. Observed comparatively few medusæ.
- August 19.—Large Chrysaora melanaster, 18 inches across umbrella, washed up on beach.
- August 29.—Picked up a large Aurelia labiata on the beach. Ovaries discharged.
- August 31.—Saw another large Aurelia on the beach,
- September 11 .- Observed one red Cyanea.
- September 15 .- Observed two Aurelia labiate.
  - Cyanca postelsii very abundant; mostly dead or dying. Observed one or two very
  - Two or three Staurophora mertensii washed up on the beach, rather mutilated.
- September 17.—Beroë roscola very plenty out among the loose ice, three or four miles from the shore.

September 20.—Observed a very large Beroë roscola, five inches long, and one Aurelia labicta, in the shoal water close to the shore.

September 28.-Much loose ice.

Beroë roscola and Cyanca postelsii abundant and large.

#### 1863

August 6 .- Water open inside "barrier."

Beroë roscola; about three inches long; very plenty in the pools along the shore.

August 8 .- Water outside the "barrier" full of acalephs. Strong NE. current.

Beroë roscola: large and very abundant.

Mertensia orum: large and very abundant.

Pleurobrachia rhododactyla: large and very abundant.

Sarsia rosaria; plenty and large.

Turris? sp.; plenty and large.

Appendicularia sp.; in enormous numbers of large size.

No acalephs were observed inside the grounded ice.

August 9.—Temperature of water, 34° to 36° F. Inside of grounded ice found surface life abundant.

Sagitta sp.; one taken.

Appendicularia sp.; in myriads.

Beroë roscola; large and small, abundant.

Pleurobrachia rhododactyla: abundant.

Cyanca postelsii; not plenty.

Sarsia rosaria: plenty and large.

Turris? sp.; plenty and large.

August 10 .- Strong NE. current. Temperature of water, 37° F.

Water filled with Appendicularia sp.; both animals and "houses."

Beroë roscola; large and small; very plenty.

Mertensia orum: not plenty.

Gemmaria? sp.; not plenty.

Sarsia rosaria; plenty, large, and flourishing.

August 11.—Beroë roscola; in myriads.

Chrysaora melanaster; abundant in all stages, from Ephyra, about 35 inches in diameter, to adult.

Turris? sp.; very plenty.

August 12.—Berov roscola; plenty. Water full of small white grains, apparently larvae of some description, though their structure could not be made out under the microscope.

August 15.—Very strong NE, current. Many "houses" of Appendicularia sp. drifting about and a good many of the animals free or partially extricated.

Beroë roscola; plenty.

Pleurobrachia rhododactyla; a few.

Bolina sp.; a few.

Cyanca postelsii; one or two small yellow ones.

Chrysaora melanaster; a few dead or dying at the bottom.

Gemmaria? sp.; plenty.

Sarsia rosaria; plenty.

Turris? sp.; plenty.

Sagitta sp.; a few specimens.

August 16.—Life in water as yesterday, but less plenty.

Until August 28, the time of the party was so occupied with the work of closing the station that no zoological observations could be made.

August 28.—Limacina pacifica; abundant, and myriads of the "white grains" above noted.

*telsii.* vater,

Tem-

Sea

rature are of

were

nacina

m the

very

August 29.—Crossing the mouth of Peard Bay. Temp. of water 42° F. Observed a few Limacina pacifica: "white grains" very plenty. Beroë roscola and other acalephs rather abundant at night.

#### BERING SEA.

September 4.-Latitude 65° 16' N., longitude 161° 30' W.

Aurelia labiata; not plenty.

Cyanca postelsii; not plenty.

Staurophora mertensii; not plenty.

September 8 .- Anchored off St. Michael's.

Aurelia labiata; not plenty.

Cyanea postelsii; not plenty.

September 9,-Anchored off St. Michael's.

Aurelia labiala; not plenty.

Cyanca postelsii; not plenty (one red one).

September 12.—In Norton Sound. Water at noon full of Aurelia labiata of large size and apparently spawning. A few Cy.inco postelsii observed.

September 13.—In Norton Sound. A few acalephs only observed. We had very rough weather from Norton Sound to Unalaska and observed no surface life.

September 21.—Unalaska. Observed in shoal water close to the beach a peculiar large acaleph about a foot across the umbrella. Closely allied to Aurelia, with very short marginal tentacles, and rather short labial happets. Color, a rich violet blue.

The weather in crossing the Pacific Ocean from Unalaska to San Francisco was generally rough and no observations of any importance could be made.

### C.—LIST OF BIRDS NOTICED AT PLOVER BAY, EASTERN SIBERIA, AUGUST 21 TO 25, 1881.

Anthus sp.; \* rather common round the Eskimo village.

Corvus corax; abundant and remarkably tame round the houses.

Strepsilus interpres; fairly abundant.

Actodromas maculata: one taken.

Actodromas bairdi; one taken badly mutilated.

Pelidna alpina americana?; one immature male taken.

Erewnetes pusitlus; fairly abundant in small flocks.

Phalaropus fulicarius; one small flock seen.

Somateria v-nigra; quite plenty; mostly females and young two-thirds grown,

Phalacrocorax dilophus? ; very plenty.

Rissa tridactyla : plenty.

Larus cachinnans ?;\* plenty and very tame.

Stercorarius parasiticus; several seen flying around the bay in clear weather.

Fratercula corniculata; plenty; one taken.

Lunda cirrhata; plenty.

Ciceronia pusilla? ;\* very numerous in good-sized flocks.

Uria grylle; very numerous.

Lomeia arra?; \* plenty.

These observations were confined to the immediate neighborhood of the "sandspit," where we lay waiting for clear weather to make time-observations at the United States Coast and Geodetic Survey station.

201

## METEOROLOGY.

#### INTRODUCTORY.

I. Meteorological observations were begun on October 18, 1881, and continued without interruption until the station was closed on August 27, 1883. They were then renewed on board of the schooner Leo, and continued till 1 a. m., October 7, 1883, when the vessel was inside the Golden Gate.

From the opening of the station until June 5, 1882, the thermometers and hygrometers were exposed in a shelter placed on the north side of the back storm-porch (see plan of station, pl. 2). This consisted of a box of galvanized iron louvre-work, with a flat roof of the same material, 5 feet long and 4 feet broad, mounted on posts 3 feet above the ground. This was inclosed by wooden louvre-work blinds on the three exposed sides, reaching to the ground, and had a wooden floor. On June 5, 1882, the instruments were removed to a larger and more convenient shelter, farther away from the quarters, extending along the northern side of the building from the northwest corner, and entered by a door at this corner (see plan, as above). This was made of wooden louvrework blinds, fastened to studding, with sealskin deprived of the hair fastened up inside, so as to inclose an air-space of 4 inches open above and below. The roof was of walrus-hide. The shelter was 16 feet long by 4 feet broad, and reached up to the eaves of the building.

The thermometers, &c., used in the observations on the voyage home, were mounted in a shelter of galvanized iron louvre-work, lashed on the starboard side of the quarter-deck.

The barometers were hung in the southeast corner of the quarters, near the window. The wind-vane was placed on the roof, north of the ridge-pole, so that the rod passed down through the ceiling of the wash-room. The anemometer was first mounted on the ridge-pole, at the west end of the building, but on the completion of the bastion, June 15, 1882, was removed to the top of this. The self-register of the anemometer was on the mantel-shelf in the quarters, and the batteries on the shelf in the wash-room. The rain-gauge occupied the place of the anemometer when this was removed.

During the extremely low temperatures it was found impossible to get satisfactory results with the wet- and dry-bulb hygrometer, and the relative humidity was accordingly observed with the hair hygrometer.

The highest temperature observed during the occupation of the station was 60 $^{\circ}$ .5, the lowest  $-52^{\circ}$ .6, giving a range of 113 $^{\circ}$ .1.

Tables showing pressure of air at Ugloamie from October, 1881, to August, 1883,

Wet bulb reading higher than dry bulb. Interpolated. Below the scale § On and after January 10, 1882, until August 27, 1883, "elative hamility taken from hair hygrometer."

Table showing the moisture of the air at Uglaamie from October, 1881, to August, 1883—Continued.

[Height of the hygrometer above the surface of the ground, 4 fest. Washington mean time. Correction reduced to mean local time, - 5 hours 17 minutes.]

# Statement showing the direction and velocity of the wind at Uglaamie from October, 1881, to August, 1883-Continued.

Height of an emometer above surface of ground, 28 feet. Washington mean time. Correction to reduce to mean local time. —8h 17m. Velocity given in miles per hour.]
